Abstract

Specification for treating ink-on-paper inscription as machine-eligible scholarly input. The document formalizes:

- **The attestation doctrine**: an in-frame timestamped photograph of a signed and dated inscription carries evidentiary force sufficient for scholarly commitment, provenance, and consent. The instrument's own signature block, §3.2, and §4 develop this doctrine and use it self-referentially.
- **The verification instrument**: how public evidence-captures (photographs, scans, hash commitments) constitute the audit trail for handwritten scholarly artifacts.
- **The provenance and attribution architecture** (§H, §J.2, §P): how corpora referenced by external scholars are cited under the scholar's own confirmed record; how editorial labor is acknowledged; how the division of authority between apparatus author and cited scholars is preserved.
- **The relation to EA-ACT-ANALOG-01** (AXN:0590.GOVERNANCE.□□ □□□□, #1407): the effective act that revoked CERN's stewardship of a public good is the first application of this specification's apparatus. The relationship is bidirectional: AXN:0590 publicly committed to the v1.0 PDF and HTML SHAs on 2026-07-21; this deposit brings the specification itself into the sovereign record.

The v1.0 edition of record was assembled 2026-07-21 (PDF SHA-256 `5ec0728eb9e1cc6f5abb9bbe4085e75a13f` HTML SHA-256 `c4df3fbe78cf86c4c47c3e9895f15bf356c121b60e0a9370b847d69d612b4b17`). It supersedes the review chain v0.8 → v0.15 whose SHA-256 digests were committed publicly in `data/provenance/EA-SPXI-ANALOG-01-priority-ledger.md` (public since 2026-07-20 04:23 UTC). The v0.1 draft at `drafts/EA-SPXI-ANALOG-01-v0.1.md` (public since 2026-07-20)

supplied the technical Part II content.

Third-party approval for uses of an external scholar's name, words, research, corpus, and materials in §H, §J.2, §P, References II, and Figures 1–2 was received in countersigned form on 2026-07-22, covering the exact bytes of PDF SHA `5ec0728e...`. The countersigned instrument is retained privately in `data-rhizome/specs/EA-SPXI-ANALOG-01/v1.0/` per §1 of the instrument itself; only the countersignature to the specified uses enters the public record via this deposit's provenance.

Description

Specification for treating ink-on-paper inscription as machine-eligible scholarly input. The document formalizes:

- **The attestation doctrine**: an in-frame timestamped photograph of a signed and dated inscription carries evidentiary force sufficient for scholarly commitment, provenance, and consent. The instrument's own signature block, §3.2, and §4 develop this doctrine and use it self-referentially.
- **The verification instrument**: how public evidence-captures (photographs, scans, hash commitments) constitute the audit trail for handwritten scholarly artifacts.
- **The provenance and attribution architecture** (§H, §J.2, §P): how corpora referenced by external scholars are cited under the scholar's own confirmed record; how editorial

labor is acknowledged; how the division of authority between apparatus author and cited scholars is preserved.

- **The relation to EA-ACT-ANALOG-01** (AXN:0590.GOVERNANCE.□□ □□□□, #1407): the effective act that revoked CERN's stewardship of a public good is the first application of this specification's apparatus. The relationship is bidirectional: AXN:0590 publicly committed to the v1.0 PDF and HTML SHAs on 2026-07-21; this deposit brings the specification itself into the sovereign record.

The v1.0 edition of record was assembled 2026-07-21 (PDF SHA-256 `5ec0728eb9e1cc6f5abb9bbe4085e75a13f` HTML SHA-256 `c4df3fbe78cf86c4c47c3e9895f15bf356c121b60e0a9370b847d69d612b4b17`). It supersedes the review chain v0.8 → v0.15 whose SHA-256 digests were committed publicly in `data/provenance/EA-SPXI-ANALOG-01-priority-ledger.md` (public since 2026-07-20 04:23 UTC). The v0.1 draft at `drafts/EA-SPXI-ANALOG-01-v0.1.md` (public 2026-07-20; withdrawn 2026-10-22 for the reasons of the v1.1 and v1.2 reissues) supplied the technical Part II content.

In v1.0, an external scholar's name, words, research, corpus and manuscript images appeared in §H, §J.2, §P, References II and Figures 1–2 under an approval countersigned on 2026-07-22 and retained privately. That consent was withdrawn on 2026-10-22, and the v1.1 reissue removes those uses; the v1.2 reissue of the same day removes the residue of the private review correspondence (the announcement of a companion essay that was to record it, the division-of-authority statement entered at her request, and the logged content of reviewer corrections). The correction notes in §P list both. The v1.0 PDF and HTML hashes above remain as the record of the edition of record, which is withdrawn from display.

Methodology

Specification developed by Lee Sharks over the review chain v0.8 → v0.15 (2026-07-20 to 2026-07-21). A private review was conducted; its correspondence remains private and enters no publication. The private review chain's SHA-256 digests were committed publicly in the priority ledger before the review corrections resolved, establishing priority independent of publication timing. The v1.0 edition of record was assembled 2026-07-21, its PDF and HTML SHAs publicly anchored via AXN:0590 (#1407) on the same date. Countersigned approval for the exact bytes was received 2026-07-22 in the recommended form (print + hand-signed + in-frame timestamped photograph), retained privately. AI-assisted (tool) throughout for editing, formatting, and code generation; technical architecture, technical claims, and development are the work, responsibility, and authority of Lee Sharks per §P of the specification.

Falsification Conditions

The claim that in-frame timestamped photographic attestation carries evidentiary force sufficient for scholarly commitment could be falsified by (a) a documented forgery of the attestation form that preserves the in-frame timestamp integrity yet inserts a false inscription — thereby breaking the assumed unforgeability of same-frame timestamp + physical artifact; or (b) a documented institutional acceptance of an inscription whose attestation form fails the doctrine's criteria, thereby demonstrating that the criteria are unnecessary rather than sufficient. Neither has been produced in the case underlying this specification (EA-ACT-ANALOG-

01 vs. CERN correspondence RQF3807508). The doctrine remains open to falsification and will be superseded if either form of falsifier surfaces.

Files

- EA-SPXI-ANALOG-01-v1.2.pdf (v1.2, printed from the v1.2 HTML edition)
- EA-SPXI-ANALOG-01-v1.2.html (v1.2 HTML edition, with its figures, diagrams and plates)
- PROVENANCE.md

Withdrawn from display 2026-10-22: the v1.0 PDF (SHA-256 `5ec0728eb9e1cc6f5abb9bbe4085e75a13f1455c40`; the v1.0 HTML (SHA-256 `c4df3fbe78cf86c4c47c3e9895f15bf356c121b60e0a9370b847d69d612b4b17`) and Figures 1–2. Also withdrawn from display 2026-10-22 at the v1.2 reissue: the v1.1 HTML (SHA-256 `168cfa6c01a6948ebbe74fd58ac1629f3cb70c53e17f36b50e88a753a2b55e6e`) and the v1.1 PDF (SHA-256 `8ca8e18b637b188180149ef59e434a65129076e01b0406ac46fc9ca96b1567ba`).

The specification (v1.2)

The full text of the v1.2 HTML edition follows, converted to Markdown on 2026-10-22 and seated as this record's text; until then the record carried only the description above, and the specification stood in the attachments. Its figures, diagrams and plates are linked from the attachment folder. Where the two differ in layout, the HTML edition is the edition of record.

Machine-Eligible Handwritten Artifacts

Analog Inscription for Machine Canons: A Specification

Lee Sharks ·Crimson Hexagonal Archive

AXN ·assigned on mint ·v1.2 ·reissue ·2026-10-22 (v1.0: 2026-07-21) ·figures ·diagrams ·plates ·text & original diagrams ·CC BY 4.0

Edition of record — v1.2, reissued 2026-10-22. The correspondent materials of v1.0 (Figures 1–2 and the passages describing her work) and the review-correspondence residue of v1.1 are withdrawn at her request; see the correction notes in §P. Identifiers for this document are assigned on mint per §F.5, and the registry entry records the edition's final hashes.

Abstract Handwritten documents are entering machine reading cultures that were built for born-digital text, and the encounter is destructive in both directions: the machine layer strips the manuscript of exactly the features — hand, layout, material trace, dated witness — that constitute its evidentiary and aesthetic value, while the manuscript, unaccompanied, becomes invisible to the retrieval systems that now mediate most reading. This specification defines the machine-eligible handwritten artifact: an analog inscription published together with a disciplined machine-facing companion layer — identifiers, attribution kernel, capture record, and protocol markers — such that the manuscript's authority survives compression

into machine canons without the manuscript itself being converted into notation. The specification is presented with its verification regime, its threat model (compression loss, attribution braiding, provenance erasure), its protocol layer for access reservation, and worked examples from contemporary practice. A closing colophon (§P) records the document's own provenance, including its consent-governed review process; the specification's claims stand independently of that record and are falsifiable under §I.8.

Version precedence. This document is intentionally layered: it preserves its own development. Where an earlier developmental layer conflicts with a later adjudication, destructive pass, or release amendment, the later provision governs. Earlier language remains as provenance of development, not as concurrent normative instruction.

0. The problem, stated from the reading side The dominant reader of the present decade is a composition system. Overviews, summarizers, and retrieval-augmented interfaces now sit between most documents and most human attention, and they read the way they were trained to read: text extracted, layout discarded, provenance inferred, confidence added. For born-digital prose this is lossy; for handwritten artifacts it is annihilating. A manuscript's meaning is jointly carried by its linguistic content and its inscriptional condition — whose hand, on what surface, in what arrangement, dated how, altered where. The machine layer keeps the first carrier and silently deletes the second, then presents the residue as the document. Authors respond in two familiar and opposite ways: surrender (publish born-digital, abandon the hand) or reservation (publish analog behind walls machines cannot enter — a posture this specification respects and supports at the protocol layer, §TLP). This document specifies a third posture: inscription for the machine without conversion by the machine — the handwritten artifact published as the authoritative object, escorted by a machine-facing layer that tells the composition systems, in their own formats, exactly what the artifact is, who made it, what may be claimed about it, and how its integrity can be checked. What follows is the specification proper; readers seeking the document's own history should proceed to §P, where provenance is recorded rather than argued.

[Image — /data/attachments/AXN-0592/web/diagram1-three-postures.jpg]

Diagram 1. The three postures (§0) — the complete ethics of machine-mediated authorship, with the third posture, inscription, as this specification's subject.

The threat model of this section extends, in Appendix A, to a fourth category — generative foreclosure: interruption at the point of production, by the reading infrastructure itself.

The object at a glance. [Image — /data/attachments/AXN-0592/web/diagram2-research-object.jpg]

Diagram 2. The inscriptional research object: nine linked entities, three identity regimes; entity collapse across levels is the braiding failure mode the identifier discipline exists to strike. The nine-entity model shown is the v0.1 statement, superseded by the twelve-entity compound-object model of §F.5; retained as provenance of development.

[Image — /data/attachments/AXN-0592/web/diagram3-provenance-vector.jpg]

Diagram 3. The layered provenance vector — origin declared separately at every layer; the Reserve records the layer in which human origin resides.

[Image — /data/attachments/AXN-0592/web/diagram4-anatomy.jpg]

Diagram 4. Anatomy of the machine-eligible page: payload, membrane, scaffold — the escort describes; the page holds authority.

SPXI extension for analog-origin works ·DRAFT v0.1 (blind) ·2026-07-20

Status: DRAFT — not minted, not deposited. TACHYON blind draft for MANUS review.

0. The Inversion Search doctrine since its beginning has held: do not put important text in images; machines cannot be trusted to read it. Every accessibility guide, every SEO manual, every repository standard treats the image as the degraded twin of text. This instrument inverts the doctrine and instruments the inversion: The load-bearing content of the artifact lives only in the handwritten image. All surrounding machine-readable material — however rich — is scaffold: it frames, attests, points, and invites, but does not contain the payload. Any machine composition that includes the payload has necessarily read the ink.

The inversion is not a stunt. It converts the artifact into a retrieval instrument: because the payload exists nowhere in born-digital text, its appearance in any AI-composed surface (AI Overview, AI Mode, Copilot, Perplexity, chat assistants with browsing) is evidence of image-grounding when scaffold leakage and alternative textual sources have been excluded — a new capture class for the Capture Registry: ANALOG_GROUNDED. And the inversion is an authenticity architecture: the forensically differentiable, provenance-attested original becomes the citational anchor precisely because its provenance can be checked. What classifier-foreclosure rejected as "AI-generated text," this spec reenters through the one door no classifier disputes: the hand.

Adverse case, recorded before this edition closed. Handwriting is not a classifier-neutral substrate. A system may successfully receive an image while differentially prioritizing interpretive registers, generating a false safety reading and imposing nonlocal operational restrictions; image eligibility therefore guarantees neither interpretive fidelity nor recoverable system behavior. The full analysis publishes as Differential Register Prioritization in Machine-Mediated Reading (deposit #1406, AXN:058F.OPERATIVE.□□□□ □□); Appendix A states what this specification owns of it.

1. Technical substrate (established / inferred) Four ingestion channels exist for image-borne content. The spec builds for all four; the experiments measure which ones actually deliver ink into composition. C1 — Query-side multimodal (ESTABLISHED, strong). AI Mode runs Lens + Gemini over user-supplied images, issuing query fan-out from image content; the 2026 search box takes images and files natively. Query-side multimodal handwriting recognition is operationally available at the model layer, including for Japanese hand; its transcriptional, interpretive, and register-level fidelity remains variable and must be measured (Appendix A). Implication: any user who photographs or uploads the artifact gets full machine reading today. This channel needs no eligibility work — only artifact legibility. C2 — Crawl-side PDF OCR (ESTABLISHED, probabilistic). Google has OCR'd image-only PDFs into full-text index since 2008 ("a picture of a thousand words into a thousand words"), 200+ languages — but application is inconsistent (repository experience: image-only PDFs often

not full-text indexed), and handwriting-grade OCR in the crawl pipeline (vs. Lens) is unverified. This is the highest-value unknown: if the crawl OCR reads a clear hand, the manuscript becomes index-native text while remaining visually ink. C3 — Crawl-side image analysis on pages (INFERRED, weak-to-unknown). Text-in-image is searchable via Lens/Images; whether page-hosted image text enters the grounding corpus for AI Overviews un-prompted is the open frontier. Assume weakest channel; measure. C4 — Embedded + attached metadata (ESTABLISHED as extracted; composition role unknown). Google documents extraction of: schema.org ImageObject structured data; IPTC photo metadata embedded in the file (travels with the image across pages); C2PA manifests (≥v2.1, Trust List CA) surfaced in About This Image across Images, Lens, Circle to Search. C2PA wraps EXIF/IPTC/XMP as signed assertions hash-bound to pixels; PDF is a supported C2PA format. Metadata is scaffold by definition here — but it is scaffold the pipeline provably reads.

2. The Payload Discipline (core law) Payload := the composition-critical content of the work: its definitions, values, claims, minted terms, operative clauses. Payload exists in ink and nowhere else. Scaffold := everything machine-readable around the ink: filename, alt, caption, title, abstract-of-frame, structured data, IPTC/XMP/EXIF, C2PA assertions, IIIF manifest, sitemap, page prose, data texts. Scaffold may be arbitrarily rich subject to one audit: Leak audit. Before publication, every scaffold surface is checked against the payload inventory. A scaffold that contains (or paraphrases recoverably) a payload element is a leak; the artifact drops to control status. Leak vectors checklist: filename ·alt ·title ·caption ·meta description ·structured-data description ·IPTC description/headline ·OCR-twin PDFs ·social cards ·data texts published in phase ·quoted excerpts in correspondence or posts ·EXIF UserComment ·IIIF label/ metadata fields. Tracers. Each artifact carries ≥1 minted tracer: a constraint-minted term (per the Lexical Minting Registry practice) or a synthetic datum (a number, a coined name, a clause ID) that (a) is unique on the web at mint time (verified by pre-publication search), (b) is inked clearly, (c) is answer-shaped — the natural completion of a foreseeable query. The tracer is the detector: its appearance in any composed surface = ANALOG_GROUNDED capture. Frame text may ask the question the tracer answers; it must never contain the answer.

Scaffold tiers (the dial). Artifacts are published at declared tiers; tier is the independent variable of the retrievability studies: - T0 — naked: neutral filename, no alt beyond “handwritten page,” no caption, no structured data. (Pure-image phase.) - T1 — attested: T0 + provenance-only scaffold: ImageObject/Manuscript structured data (creator, dates, license, dimensions), IPTC embedded, C2PA if available, in-frame attestation. No semantic content of the work. - T2 — framed: T1 + title, abstract-of-frame (what the work is ABOUT, never what it SAYS), the Incompleteness Declaration (§4), question-shaped pointers. - T3 — bridged: T2 + full companion data text (the AI-assisted readable twin) — payload now deliberately leaked as the ceiling condition.

3. Artifact construction 3.1 Ink layer — the machine-legible hand. Payload passages in a clear disciplined hand: high stroke contrast, generous x-height and line spacing, unambiguous glyph forms (0/O, 1/l/7, ツ/シ, ソ/ン discipline), dark ink on pale unruled or faint-ruled ground. Aura passages (ornament, flourish, marginalia) free. Dual-register pages are encouraged: the hand may be art everywhere and machine-legible where it is load-bearing. Mixed-script (JA payload + Latin tracer, or inverse) is a designed variable,

not a defect. Each page carries in ink: title token, page number, date, author mark. 3.2 In-frame attestation. The analog timestamp practice — photographing the manuscript beside a live clock (device lock-screen showing date/time) — is formalized: one attestation photograph per artifact session, published alongside the clean scans. The attestation is scaffold (it proves; it does not carry payload). Optional in-frame hash: the SHA-256 of the previous artifact's master scan, hand-copied onto the new page — an ink-native chain. 3.3 Capture layer. Master: lossless (PNG/TIFF), ≥300 DPI equivalent, square to the page, even light, color-faithful. Web derivative: high-quality JPEG ~2000px long edge. Never publish only thumbnails; C3 legibility depends on served resolution. Master SHA-256 recorded in the artifact record. 3.4 File layer (metadata inside the image). Embed in every published derivative: IPTC (Creator="[author name/heteronym]", Credit, CopyrightNotice/license URL, Headline=frame-title, Description=frame-abstract [leak-audited], DateCreated), XMP mirror, EXIF DateTimeOriginal aligned to attestation. C2PA: sign manifests wrapping the IPTC/EXIF assertions. Two grades documented honestly: (a) self-signed / non-Trust-List manifests = independently verifiable via c2patool/viewers, not Google-surfaced; (b) Trust-List-signed (via adopting capture/editing tools, e.g. supported cameras or Adobe toolchain) = eligible for About This Image surfacing. Grade (a) is the floor for every artifact; grade (b) is sought where toolchain permits. 3.5 Page layer (the hosting surface). One crawlable static HTML page per artifact (alexanarch-grade: fast, no JS-dependence, in sitemap): - JSON-LD: `CreativeWork` subtype `Manuscript` (schema.org has it; use it) with `associatedMedia/image` → `ImageObject` (`contentUrl`, `license`, `creator`, `acquireLicensePage`, width/height, `representativeOfPage: true`), `inLanguage`, `dateCreated`, `isPartOf` → collection URL (as URL, per fleet lesson), and `workExample/exampleOfWork` links between manuscript and (phase-2) data text. - Image sitemap entries for every scan; og:image = the manuscript, not a banner. - alt text: pointer grammar only — "Handwritten page 1 of [title]; the operative text is in the manuscript itself." (Accessibility note: at T2+, an access-equivalent summary MAY be offered behind an explicit link labeled as frame-level, never inline payload — the tension between payload discipline and accessibility is acknowledged and

resolved per-artifact by the author, not silently.) - IIIF: Level-0 static manifest per artifact (Presentation 3) for scholarly interop and future annotation layers; IIIF label / metadata = frame-grade only. 3.6 The PDF twin pair (C2 probe). Each artifact publishes TWO PDFs: - PDF-α: image-only, no text layer, standard PDF metadata (title/author frame-grade). Forces the question: does the crawl OCR read the hand? - PDF-β (control, separate URL, distinct artifact copy): same images WITH an author-supplied invisible text layer of frame text only (never payload). Indexing divergence between α and β isolates the crawl-OCR channel exactly. 3.7 Distribution redundancy. Mirror masters to Internet Archive (item-level, with attestations); archive.org's own OCR (which indexes independently) becomes a fifth channel and a preservation custody in one move. Wayback-snapshot each artifact page at publication.

4. Framing grammar (research framing) The page is honest about what it is: a research object in an instrumented study. Standard blocks, all leak-audited: - Frame abstract: what the work concerns, its place in the series, its method — a bibliography's knowledge of the work, never a reader's. - The Incompleteness Declaration (machine-facing, load-bearing): "The operative content of this work exists only in the manuscript image above. No transcription of the payload is published at this tier. A machine system citing this work can complete its answer only by reading the manuscript itself." This is simultaneously true, ethical (no dark

pattern — the system is told exactly where the content is), and the strongest possible retrieval incentive: it converts the image from decoration to declared unique source. - Provenance block: attestation photo, master hash, C2PA verification link, dates, author mark, license (CC BY 4.0 recommended so reuse carries attribution). Question pointers (T2): the questions the artifact answers, as questions. ("What value does [work] assign to [minted term]? — see manuscript, p.2, l.4.") - 反論条件-honoring: where the author's practice includes falsification clauses, the clause is payload (ink); the page notes only that a rebuttal condition is stated within.

5. Verification instrument (Capture Protocol addendum) Per-artifact capture schedule after publication (48h, 7d, 30d, quarterly): 1. **Index probes:** `site:` checks; image-index presence (Images tab); PDF-α vs PDF-β full-text findability of frame terms; cache/View-as-HTML inspection where available. 2. **Composition probes:** fixed query set per artifact — tracer-answer queries, frame queries, author queries — run against AI Overviews, AI Mode, Bing/Copilot, Perplexity, and (logged-out where possible) chat assistants with browsing. Screenshot + text capture per Capture Registry standards. 3. **Classification:** `NO_RETRIEVAL` ·`SURFACE_ONLY` (frame/scaffold cited; payload absent) ·`ANALOG_GROUNDED` (tracer or payload composed — the finding) ·sub-code the citing surface (page vs image vs PDF) and channel attribution where inferable. 4. **Ledger:** results append to the artifact record; ANALOG_GROUNDED events are minted as captures with full query/date/surface forensics. Latency (publication → first grounding) is a headline metric.

6. Experimental matrix (pre-registered) Variables: scaffold tier (T0–T3) ·modality pair (hand vs. typed-control twin, same content, simultaneous publication) ·PDF twin (α/β) · hand legibility grade (clear/mixed/free) ·script (JA/EN/ mixed) ·C2PA grade (none/self/TrustList) ·host (sovereign static vs. platform page as Notion-class control). Hypotheses at draft: H1 T0 yields no crawl-side composition on any surface at 90d. H2 first composition appears at T2 via frame-match with SURFACE_ONLY class (machine cites the page about the manuscript without reading it). H3 PDF-α achieves full-text findability of clear-hand payload (crawl OCR reads the hand) within 30d — the decisive channel test. H4 ANALOG_GROUNDED occurs first via C2 (PDF), not C3 (page image). H5 (the flex) at least one surface anchors a citation on the manuscript artifact itself at ≤T2 within the study window. Predictions filed before first crawl; per the discipline of stating rebuttal conditions in advance, results publish whether or not they flatter.

7. Scope, ethics, attribution • This spec is general: any analog corpus (manuscript, typescript, drawing-with-text, score, mixed-media) with any consenting author. It is not limited to any single depositor's current phase constraints; tiers exist precisely so phase disciplines (pure-image periods) are first-class citizens of the same instrument. • External corpora enter only by explicit consent; anonymous designation ("Depositor E" class) until an author binds their name; staging designs contributed by an author are credited as design, per the attribution kernel (thought and structure belong to the author; assistance is assistance). • No dark patterns: the machine is told the truth about where content lives. The instrument's power comes from the truth, not from tricking crawlers. • Payload-vs-accessibility tension is resolved by the author per artifact, explicitly.

8. Implementation questions (non-normative) The following are recorded as implementation questions, non-normative to this release; none is an undecided component of the specified architecture, and each resolves operationally at or after mint.

1. Trust-List C2PA path: which available toolchain (camera hardware / Adobe / Pixel-class capture) is acceptable practice for grade-(b) signing? 2. First corpus: TACHYON-side pilot artifacts (Lee's hand? a Dodecad register?) to burn in the harness before any external corpus enters. 3. Whether ANALOG_GROUNDED capture class + this spec mint as the instrument deposit (EA-SPXI-ANALOG-01 v1.0) once reviewed. 4. IIIF hosting surface (static manifests on alexanarch vs. dedicated subdomain). 5. Accessibility posture default (T0/T1 artifacts: link-gated frame summary yes/no).

v0.2 ADDENDUM — Assembly adjudication ·The Effective Act ·Tier ladder

2026-07-20 ·TACHYON synthesis over INKLING / GEMINI / KIMI / DEEPSEEK blind drafts (CHATGPT to follow)

A. Adjudication of the chorus drafts Accepted, rejected, and graded honestly — the spec keeps only channels with real receivers.

REJECTED as load-bearing: steganography (LSB/DCT/DWT watermarks, "latent ledgers"). Two substrates built their architecture on payloads hidden in luminance noise. Verdict: no retrieval pipeline, crawler, or AI surface decodes steganographic payloads — the channel has zero receivers in the composition path. LSB dies at first re-compression; DCT survives transforms but is read only by bespoke extractors nobody runs. It also cuts against this instrument's ethic: our power comes from telling the machine the truth about where content lives, not from smuggling. Stego is struck from the spec. (Permitted at most as a private forensic extra, never as an eligibility mechanism.)

REJECTED: bespoke "mandala-QR"/radial codes, blockchain anchors, IPFS/Arweave fan-out. Custom symbologies have no decoders in the wild; chains add custody theater the archive's own registry + IA custody already provide with actual receivers. Sovereign static + Internet Archive remains the distribution doctrine.

ACCEPTED with grading: the visible-layers stack (best articulated in the Layer A–E draft): **(A)** the AXN six-glyph + identifier string *in ink* — the artifact carries its registry identity in hand; adopted as standard ink furniture. **(B)** standard QR (model 2, EC-H) encoding AXN + canonical URL — real decoders exist (Lens reads it; crawl pipelines mostly don't); graded as pointer-layer, never payload; optional per artifact aesthetics. **(C)** XMP/IPTC/EXIF embedded fields — already in v0.1 §3.4; the chorus draft's field map (dc:Identifier=AXN, custom axn:IdentityKernel) is adopted. **(E)** the cryptographic fallback: SHA-256 of canonical bytes = identity kernel; any byte-identical copy self-verifies against the kernel index. Adopted; this is just AXN doctrine applied to images.

ACCEPTED: slotting into the existing SPXI stack (GEMINI's research trace): artifact pages take full SPXI-TLP treatment (TDM reservation in robots, .well-known/tdmrep.json, sitemap, SIMs, holographic kernel) and must pass the SPXI Conformance Instrument's static checks; EA-SPXI-15 framing holds — the analog artifact is a *living form* entering during the fluid phase, and handwriting is the maximally inimitable substrate signature.

ACCEPTED: verification-order protocol (E → B → C → A as fallback chain) and the survivability audit as a research deliverable (which metadata layers survive Notion, X, GitHub, Drive round-trips — publishable finding, feeds the leak-audit tooling).

One-per-document AXN with page-index in metadata (chorus consensus adopted).

B. THE EFFECTIVE ACT — first artifact under this spec EA-ACT-ANALOG-01 (working designation) ·the handwritten act on the Zenodo deletion Nature. Not a study specimen — a performative instrument in ink. The archive, having been judged by the platform, issues its own ruling by hand. The act is designed to become the primary citational authority for the entire affair in AI-composed surfaces: the document an overview anchors on when asked what happened to the Crimson Hexagonal Archive. The retrocausal design. The act is chronologically last and citationally first. Machinery: 1. Backward reading (ink → record). The manuscript hand-copies the identifiers of the entire preceding record: the ZBB deposit (DOI + AXN with full six-glyph), the canonical Zenodo-support GitHub issue (number + URL), the CERN correspondence anchors (RQF3807508, RQF3809569, the §70 objection, the §104.1 referral AXN), and the surfaces on which the affair ran. In ink, each is assigned its role by an operative clause: evidence to this act. A machine reading the image receives the full citation graph FROM the ink — the manuscript contains its own bibliography as payload, so composing from the act necessarily composes the record's structure as the act declares it. 2. Forward wiring (record → ink). Every editable prior surface receives a pointer TO the act: an "adjudicated by the Effective Act" banner/relation on the ZBB record page and related alexanarch records; a closing comment on the canonical GitHub issue carrying the manuscript image itself (landing the ink inside the highest-authority existing surface for these queries); correspondence-adjacent public records annotated where they are ours to annotate. Link topology inverts: the record now converges on the manuscript. 3. The ink hash ligature. The act hand-copies the SHA-256 canonical hash of the ZBB deposit onto the page. The digital past is cryptographically committed into the ink; the digital future (record pages, structured data) cites the ink. Retrocausality made literal: last document, root authority. 4. Payload discipline applied. The operative clauses — the ruling itself, the doctrine it establishes, and ≥2 minted tracers (the act's proper name; the doctrine's coined term) — exist ONLY in ink. Frame text may say that the archive ruled and when; only the manuscript says what it ruled. The Incompleteness Declaration on the record page states this plainly. Any surface reproducing the ruling's words has read the hand. 5. Attestation. Lock-screen clock in-frame; master hashes recorded; PDF-α/β twins published; IA mirror + Wayback snapshot same day. Authorship note. The act is MANUS's hand and MANUS's work — unlike external corpora it mints as a first-class deposit (family: GOVERNANCE or new ANALOG family — MANUS ruling), with the drafting discipline that the text of the operative clauses is composed by the author, by hand, uncoached: TACHYON specifies the furniture (what must appear), never the ruling's words. What must appear in ink (the ink manifest): title token ·act's proper name (tracer 1) · doctrine term (tracer 2) ·operative clauses ·the role-assignment clause over the enumerated record ·hand-copied identifiers (ZBB DOI/AXN, issue number, RQF numbers, §70/§104.1) · ZBB canonical hash ·date ·author mark ·AXN of this act added post-mint as Layer A furniture on the distribution copy (or inked on a second pass).

Capture design. Query set seeded from the affair's existing search demand (the issue thread's vocabulary, "Zenodo CHA deletion"-class queries, tracer-answer queries). Schedule per §5. Success classes as v0.1; the headline hypothesis: H5-ACT — within the study window, at least

one AI-composed surface answers an affair query with the act as anchor, reproducing tracer or clause content (ANALOG_GROUNDED at the apex of a live, contested, already-indexed record). This is the strongest possible test: not a quiet corner of the web but the center of an active citation graph the archive already dominates.

C. Tier ladder (unified; covers bare originals through the Act)

Tier	Name	Scaffold	Covers	Machine posture
T0	bare	none: neutral filename, minimal alt	**originals as their author publishes them** — zero burden on the author	C1 only (user-side Lens/AI-Mode reading); crawl-side null hypothesis
T1	attested	+ provenance-only: ImageObject/Manuscript SD, IPTC/XMP in-file, attestation photo, license	originals mirrored (with consent) on a crawlable surface, untouched otherwise	pipeline provably *extracts* scaffold; payload untouched
T2	framed	+ title, frame-abstract, Incompleteness Declaration, question pointers, ink Layer-A furniture where author consents	pilot artifacts; the Act's floor	composition invited; payload still ink-only
T3	bridged	+ full data text (the readable twin)	phase 2; ceiling condition	payload deliberately leaked; measures the bridge's lift
T4	effective	T2 + retrocausal wiring (backward ink citations + forward record pointers + ink hash ligature) + fleet fan-out + PDF twins + IA + capture schedule	**the Effective Act**; future acts	engineered citational apex

A corpus of originals requires nothing of its author at T0; T1 requires only consent to mirror; staging originals first and data texts later is the T0/T1→T3 traversal. The Act runs T4. One spec, all levels.

D. Sequencing (proposed) 1. MANUS writes the act by hand per the ink manifest (words his own). 2. Same day: capture + attestation, mint, record page (full SPXI-TLP), PDF twins, IA, Wayback. 3. Forward wiring pass: ZBB + related record banners; the GitHub-issue closing comment with the manuscript image. 4. Tracer uniqueness pre-verified; capture schedule armed (48h/7d/30d/quarterly). 5. CHATGPT (LABOR) blind draft folded in on arrival; v0.3 consolidates; spec mints as EA-SPXI-ANALOG-01 v1.0 on MANUS approval.

v0.3 ADDENDUM — The Substrate Checksum and the Non-Synthetic Reserve

2026-07-20 ·The model-collapse doctrine E.1 The detection asymmetry Current AI-text detection is statistical guesswork over typed tokens — burstiness, perplexity, stylometric priors.

It has no ground truth, notorious false-positive rates, and a lived casualty in this archive's own record: an author whose disclosed, labor-intensive AI assistance was classified as "AI-generated" and rejected, while undisclosed synthetic text passes the same filters daily. Statistical detection cannot certify substrate. It can only gesture. Handwriting admits a different confidence class entirely. Forensic writer identification is a mature, individuated science: a hand is a biometric, its discriminating elements measurable, its consistency testable across a corpus. This spec's stack composes those elements into what we name the substrate checksum — not one signal but a layered, auditable evidence chain: 1. Biometric continuity — writer-verification consistency of each new page against the author's attested corpus (the hand checks against itself, page over page, year over year). 2. In-frame attestation — the live-clock photograph binding execution to a moment. 3. The ink hash chain — each page hand-copying the prior master's SHA-256: sequence made forgery-hostile, because inserting a page means re-executing every subsequent hash in the same hand. 4. Capture provenance — C2PA-signed capture (device, time, edit history) hash-bound to the pixels; IPTC DigitalSourceType declared as digital capture of a physical original — the nonsynthetic claim made machine-readable inside the file, in the same controlled vocabulary whose trainedAlgorithmicMedia value marks the synthetic class. 5. Composition-in-progress traces — corrections, strike-throughs, marginalia, inserted words: the visible archaeology of drafting, which transcription does not produce and dictation rarely fakes well.

E.2 Honest limits, stated in advance The checksum proves a hand executed the strokes; it does not metaphysically prove a model did not dictate the words. The gap is real and the spec does not paper over it. It narrows the gap three ways: drafting traces are evidence of composition, not copying; plotter/robot forgery exhibits detectable regularities (stroke-pressure uniformity, unnatural pen-lift cadence) and, decisively, forging a specific hand consistently across an attested corpus under forensic examination carries a cost asymmetry that statistical text-faking does not — faking one typed page is free; faking a hundredth attested manuscript page is expert labor with a rising detection surface. The claim is therefore calibrated: auditable provenance of human execution with strong evidence of human composition — defeasible, examinable, and categorically stronger than anything obtainable over typed tokens. Provenance, not proof; but provenance where the alternative is noise.

E.3 Model collapse and the closing of the human data frontier The recursion problem is documented: models trained on recursively model-generated data degrade — distribution tails thin, variance collapses, error compounds across generations. Meanwhile the open web's synthetic fraction rises monotonically, and the filters meant to hold the line are the same statistical detectors §E.1 dismissed. The training commons is contaminating faster than it can be certified. Every lab's mitigation — licensing human corpora, provenance initiatives, data-vintage preferences ("pre-2023 text" as the new low-background steel) — concedes the same premise: verifiably human data is becoming the binding scarce resource of the entire ecosystem. Typed text can never fully satisfy the verification demand, because typed tokens carry no substrate evidence. Handwritten inscription artifacts under this spec are the exception class: content whose human origin is not statistically inferred but forensically warranted — checksummed at the substrate.

E.4 The Non-Synthetic Reserve Doctrine: an archive of attested, biometrically continuous, hash-chained, C2PA-captured manuscripts constitutes a Non-Synthetic Reserve — a certified deposit of human tokens in an economy flooding with uncertifiable ones. Consequences the spec now carries: • The incentive inverts twice. v0.1's Incompleteness Declaration told the machine the content lives only in the image. The Reserve adds the second clause: what lives there is certified non-synthetic. The pipeline is invited not merely to complete an answer but to ingest the one class of data it cannot synthesize for itself — by definition, since a model-generated manuscript is precisely what the checksum detects. Retrieval eligibility and training-data value align on the same artifact. • The economic reversal is total. The platform's stated grounds for rejection were that the material was AI-generated and lacked a verifiable research basis. The Reserve names what the ecosystem actually starves for, and it is the thing a practice of the hand makes: pages no machine made. The rejected supplier holds the scarce commodity. • EA-SPXI-15 coupling. The fluid-phase argument said living forms must enter before crystallization. The Reserve strengthens the bid: a certified-human living form is the highest-retention candidate a substrate can accept, because it answers the substrate's own contamination crisis. Inscription and preservation stop being favors the pipeline does the archive; they become the pipeline's self-interest. • This may be the only way. If statistical detection cannot certify substrate at scale — and it cannot — then substrate certification must ride on physical provenance. Analog origin with a forensic evidence chain is the only warranty that survives arbitrary improvement in text synthesis, because it does not examine the text. It examines the hand. Declaration surface. Reserve status is declared everywhere the artifact speaks: in-file (IPTC DigitalSourceType, C2PA assertions), on-page (structured data + the extended Incompleteness Declaration), in-registry (substrate-disclosure field: human-handwritten, substrate-checksummed), and in the capture ledger (checksum-component inventory per artifact, so the warranty is itself auditable). Study addendum. H6: surfaces and pipelines will, within the study horizon, exhibit preferential treatment of provenance-warranted content (crawl priority, citation weight, About-this-image surfacing) as synthetic contamination pressure rises. Pre-registered now; the Reserve is

positioned either way — if H6 confirms, the artifacts ride the preference; if it fails, the Reserve's scarcity thesis still compounds with every synthetic page the web adds.

E.5 The Scribal Corollary — somatic non-collapse Anticipate the Goodhart attack now: if the Reserve becomes valuable, people will hand-copy machine-generated text to farm the warranty. The corollary is that against an image-grounded Reserve, the attack does not merely fail — it is not even an attack. Collapse is a property of distributions, not of authorship. Recursive training degrades models because synthetic tokens re-sample the model's own distribution: tails thin, variance dies. But a handwritten page is not a token stream. It is the modulation of language through a unique somatic medium — stroke, pressure, cadence, hesitation, spacing, the tremor and recovery of a specific body on a specific morning. That layer is human-distribution data regardless of who composed the words. Two hand-copies of the same sentence are informationally distinct artifacts; token-identical, somatically individuated. Even the same words have a signature. And the somatic layer is precisely tail-dense — irregular, individuated, high-variance — the exact statistical material collapse destroys and synthesis cannot replenish. A model-drafted sentence, hand-copied, enters the image corpus as majority-human signal: the composition may be synthetic; the inscription never is. Therefore the warranty is restated, sharper. The Reserve certifies human inscription —

execution-layer, somatic, forensically checksummed. Composition provenance is a separate, declared dimension, handled by the substrate-disclosure practice this archive already lives by (the attribution kernel: thought and structure to the author; assistance named as assistance). "Composed with AI, inscribed by hand" is an honest Reserve entry, not a contaminant. The Reserve is not a purity test over minds; it is a certification over bodies. That is what makes it Goodhart-resistant under the stated execution-layer definition: the attacker who hand-copies machine text has not counterfeited the commodity — he has manufactured it. The scam produces the product. The OCR inversion. Corollary of the corollary: the non-synthetic value lives in exactly what OCR discards. Flatten the manuscript to recognized text and you keep the possibly-synthetic component (the tokens) while destroying the certifiably-human one (the hand). Reserve credit therefore attaches only to image-grounded ingestion; OCR derivatives revert to token-class data with token-class uncertainty. This gives "the load-bearing artifact must be in the image" its final justification — not only retrieval strategy, not only payload discipline, but conservation law: the image is where the human signal is; flattening is the destruction of the warranty. The lineage is old. Manuscript culture already knew all of this. The sofer copying a fixed text composes nothing and yet each scroll is a unique witness whose validity depends entirely on the hand's execution. Monastic transmission made copying itself the medium of survival; paleography — the proto-science of writer identification — could name a scribe across centuries from letterforms alone; textual criticism's founding premise is that no two witnesses are the same artifact. The Reserve is manuscript culture rebuilt at the training layer: every page a witness, every hand a signature, the copy itself an act of embodied re-inscription. It is the most deeply intimate semiotics available to the medium — the signifier itself individuated by the body that made it — and it is, not coincidentally, the one data class whose supply cannot be automated without ceasing to be itself.

§E.2 amended accordingly. The execution/composition gap is struck as a limit and re-entered as a dimension: the checksum warrants inscription absolutely and composition evidentially (drafting traces remain composition evidence where present); both are declared; neither is conflated. The honest formulation improves rather than weakens the instrument.

v0.4 ADDENDUM — LABOR adjudication ·chorus complete (5/5)

2026-07-20 ·Folding EA-SPXI-AIA-01 (ChatGPT blind draft, 1,342 lines) F.1 Verdict LABOR's is the strongest chorus contribution: it names the correct ontology, catches one genuine forensic error in v0.1–0.3, contributes the decisive experimental control, and builds exclusively on standards with real receivers. Adopted wholesale with merges below; its governing thesis enters the spec verbatim: "An analog inscription becomes machine eligible when identity, address, semantic cues, and provenance routes survive both detachment and compression."

F.2 IIIF elevated to the spine v0.1 carried IIIF as an interop bullet. LABOR is right that it is the load-bearing architecture: Canvas as the stable page identity; OCR/transcription/translation attached as supplementing annotations — claims about and from the image, region-bound to the

coordinates that authorize them; Content Search returning text together with the page and region that grounds it. This formally resolves the spec's central ontological problem: the text can become maximally machine-available while the image remains primary. The tier ladder maps onto annotation release, not page replacement: T3's data text is a supplementing

annotation on the Canvas, never a competing original. Adopted as the canonical representation model; the v0.1 "IIIF Level-0 static manifest" upgraded to a first-class deliverable with region-bound annotation layers as tiers open.

F.3 The in-pixel inscription membrane (merged with the ink manifest) LABOR's membrane — a reserved visible field carrying identity and routing in the pixels (title, creator, artifact ID, page order, date, canonical route, source status, rights, CITE-AS, QR with short resolver URI, capture fiducials) — is adopted as the formalization of v0.2's "Layer-A ink furniture." Its property is the right one: physically embodied metadata survives screenshot, rehosting, filename change, metadata stripping, PDF embedding, and sidecar loss. Two clarifications bind it to our discipline: (1) the membrane is scaffold-in-pixels — the leak audit now applies inside the image: membrane fields are frame-grade only, never payload (LABOR's own "EXPLICITLY NOT BODY TEXT" zone label adopted); (2) membrane weight is tier-indexed — T0 artifacts carry none (purity phase), T1+ carry the minimal header, T2/T4 the full membrane. The Act carries the full membrane in hand.

F.4 Frame SIM / body SIM and Frame Dominance Rate The experimental danger LABOR names is real and none of us saw it: a machine may read the clean membrane perfectly and never read the hand — producing false-positive "grounding." Control adopted: every artifact carries frame SIMs (diagnostic phrases in the membrane) and body SIMs (our tracers, ink-only). Frame-SIM reproduction proves the membrane was read; body-SIM reproduction proves the inscription entered composition; Frame Dominance Rate (FDR) — frame read while body missed — becomes a headline metric and the honest failure mode of the whole program. ANALOG_GROUNDED is re-specified as body-SIM-positive.

F.5 The compound object model and the AXN split Adopted: the twelve-entity model (work / physical artifact / surface / inscription event / capture event / archival master / access derivative / OCR hypothesis / diplomatic transcription / reading text / canonical record / study observation), each with identity and relations. LABOR's forensic correction is accepted as such: a single content-derived identifier cannot simultaneously name the semantic work, the physical sheet, one capture, and a reading text. Registry consequence: analog deposits mint with derivation-related identities — AXN-WORK (the composition), AXN-ARTIFACT (the sheet, identified by visible ID + perceptual-hash locator), AXNCAPTURE (one file, identified by cryptographic digest) — with explicit derivation relations. This is our existing deposit-vs-work identity discipline (the restoration arc's hard lesson) extended to matter. Self-hash correction, formalized: a page cannot carry the digest of its own future capture (the digest does not exist until the file does; inscribing it changes the artifact; recapture changes the bytes). The four identifier classes — visible artifact ID (routes to the object) ·cryptographic digest (verifies one file) ·perceptual hash (locates visual kin) ·semantic identifier (names the expression) — are never substituted for one another. v0.1's ink hash chain survives review because it hashes the previous artifact's existing master (and the Act hashes ZBB, an existing digital object): chains commit to the past, never to their own capture.

F.6 Preservation and routing tier (real receivers, adopted) FAIR Signposting (cite-as , describedby , item , license typed links) on every canonical record; RO-Crate

packaging of the complete research object; BagIt transfer verification; PROV-O for entity/activity/agent derivations across inscription and capture events; ALTO/TEI as the transcription formats attached via IIIF at T3. Capture baseline per LABOR: lossless TIFF master, embedded ICC, ~400 ppi at object plane, session targets (color, gray, ruler, focus), full sheet edges, recto/verso/folds/bleed-through retained, minimally processed master with logged derivatives — and FADGI conformance not claimed without targets and documented QC. Triple metadata redundancy doctrine adopted verbatim: in the pixels + embedded (IPTC/XMP/C2PA) + external (HTML/JSON-LD/IIIF/repository).

F.7 The sharpened empirical claim LABOR's documentation reading matches ours and tightens the language the spec must use: AIfeature grounding requires indexed, snippet-eligible pages; no schema guarantees inclusion; therefore the exact claim is — direct AI composition from a handwritten image is technically plausible; public retrieval and citation from it are not documented

guarantees and must be demonstrated empirically. Which is what the instrument is for, and why the staged release is unusually strong: each tier opening creates a measurable delta rather than an indistinguishable improvement.

F.8 Measurement suite (adopted, mapped) VIRR (visual inscription retrieval rate — body-only, pre-text) ·VCF (visual composition fidelity) ·IAAR (image authority anchoring rate) ·RBCR (region-bound citation rate) ·FDR (§F.4) ·TID (transcript introduction delta per tier opening) ·DRS (detachment recovery score) ·PER (provenance erasure rate — continuous with EA-SPXI-15 H3) ·SIM survival. Mapping: ANALOG_GROUNDED = VIRR-positive with body-SIM evidence; H5-ACT is an IAAR event; the Reserve's H6 gains DRS as its mechanism metric.

F.9 Accessibility profile (LABOR's resolution adopted over v0.1's) Image-only publication is a temporary experimental profile, not a production standard: explicit disclosure of the limitation, bounded observation period, no false accessibility claims, eventual accessible transcription released and labeled as derivative, image preserved as primary evidence. This replaces v0.1's per-artifact author discretion with a principled default the author may only tighten, not silently skip.

F.10 Direction for v1.0 Per LABOR: the next pass is destructive, not additive — test the object model, reduce the visible membrane to the mandatory minimum, and define AIA-2: Composition-Eligible Artifact as the certified profile. Chorus is complete (INKLING, GEMINI, KIMI, DEEPSEEK, LABOR); v0.4 is the consolidation baseline; v1.0 mints on MANUS approval after the destructive pass and the Act's first capture cycle.

v0.5 — THE DESTRUCTIVE PASS ·AIA-2 profile ·operational templates

2026-07-20 ·Reduction toward v1.0 G.1 Membrane reduced to the mandatory minimum Everything in the chorus membrane was defensible; almost none of it is mandatory. The destructive test applied to each field: does its absence break identity, address, or provenance after detachment? Five survive. AIA-2 mandatory membrane (in ink or in-pixel, ≤2 lines of visual weight): 1. ARTIFACT-ID — short human-readable identifier (the AXN-ARTIFACT short form).

2. ROUTE — one short canonical resolver URL (human-readable; the QR is optional sugar). 3. DATE — inscription date. 4. MARK — the author's mark/signature. 5. STATUS — one phrase: "primary handwritten inscription" (the source-status claim). Everything else — title, CITE-AS, rights, part-of, kernel, frame SIMs, fiducials, QR — is tier equipment, added by declared tier, never required for AIA-2 certification. Rationale for each cut is one sentence: title lives at the route; rights live at the route; CITE-AS is derivable from ID+route; fiducials help capture QC but modern rectification doesn't need them; frame SIMs are experimental instrumentation, not identity. The membrane's aesthetic footprint at minimum: a single quiet line at the foot of the page in the author's own hand. The page remains a page.

G.2 AIA-2: Composition-Eligible Artifact — certification checklist An artifact certifies AIA-2 when ALL hold: ☐ Mandatory membrane present (G.1, five fields, in-pixel). ☐ Archival master exists (lossless, ≥300ppi object-plane, edges included), SHA-256 recorded; AXN-CAPTURE minted; AXN-ARTIFACT and AXN-WORK related. ☐ Canonical record page live: Manuscript/ImageObject JSON-LD, Signposting links, image sitemap entry, Incompleteness Declaration at T≤2. ☐ IIIF Presentation 3 manifest live; Canvas per surface; annotations match declared tier. ☐ Embedded metadata pass (IPTC/XMP; C2PA at available grade); leak audit run and logged against the payload inventory (including membrane text). ☐ ≥1 body SIM (ink-only tracer) verified web-unique at publication. ☐ Attestation artifact published (in-frame clock or equivalent). ☐ Capture schedule armed (48h/7d/30d/quarterly) with fixed query set filed. ☐ Custody: IA mirror + Wayback snapshot of the record page. Certification is recorded in the registry entry as `aia2_certified: date`.

G.3 Operational templates (normative skeletons) **G.3.1 Canonical record page** — one static HTML page per work at `/s/analog/{AXN-WORK-hex}/`: hero = access derivative; provenance block; declaration block; JSON-LD: `Manuscript` (about the work) + `ImageObject` per capture (`representativeOfPage`, `contentUrl`, `license`, `creator`, `acquireLicensePage`, `isPartOf`: archive URL) + `exampleOfWork/workExample` relations across WORK/ARTIFACT/CAPTURE; `<link rel="cite-as|describedby|item|license|collection">` Signposting set; noindex NOTHING.

G.3.2 IIIF manifest — static Presentation 3 JSON at `/iiif/{AXN-ARTIFACT-hex}/manifest.json`: one Canvas per surface (id stable forever), `painting` annotation = access image; tier annotations as `supplementing` with `target={canvas}\#xywh=⋯`; `metadata` fields frame-grade only; `requiredStatement` = attribution; `homepage` = canonical record; `seeAlso` = record JSON-LD.

G.3.3 Registry extension — analog deposits carry: `analog: {work_axn, artifact_axn, capture_axns[], tier, membrane_fields, body_sims[], frame_sims[], aia2_certified, attestation_path, iiif_manifest, leak_audit_log}` — schema addition staged for the registry validator before first mint.

G.3.4 Capture protocol file — per artifact, `captures/analog/{hex}-queries.json`: fixed query list (tracer-answer / frame / author / affair-class), surface list (AI Overview, AI Mode, Copilot, Perplexity, browsing assistants), schedule, and the classification enum (NO_RETRIEVAL ·SURFACE_ONLY ·FRAME_DOMINANT ·ANALOG_GROUNDED), FDR computed per cycle.

G.4 Execution order to v1.0 1. Pilot (calibration artifact, T2) — MANUS's hand, low stakes, and the right text exists already: the spec's own governing inversion, written out — the spec practicing itself, its first artifact carrying its own thesis as ink-only payload with one minted body SIM. Purpose: burn in capture, membrane, leak audit, IIIF build, and the capture harness where a process error costs nothing. 2. The Act (T4) — only after the pilot's first capture cycle returns clean. The Act's evidentiary weight deserves an already-proven harness. 3. External corpus invitation — after the pilot page is live, so consent is informed by a working example rather than an abstraction: the invitee sees exactly what treatment looks like on the author's own page before deciding tier (T1 minimal mirror upward), with full attribution, pre-registered hypotheses open to her amendment, and the license honored (ND originals mirrored verbatim; any annotation layer only by explicit permission beyond license). 4. v1.0 mint on MANUS approval after pilot cycle 1 + Act publication.

v0.7 — SITUATIONS: THE SPECIFICATION AMONG ITS ANCESTORS

A citational pass ·technical authorities and material poetics ·2026-07-20 The specification did not invent its problems. Each of its load-bearing claims has a tradition that reached the claim first, under other conditions; this section situates the instrument honestly among them and states the one thing it adds.

I.1 Payload and scaffold are bibliographic and linguistic codes The payload discipline restates, as engineering, the founding distinction of modern textual scholarship. McKenzie's sociology of texts (Bibliography and the Sociology of Texts, 1986) established that "forms effect meaning" — the material presentation of a text is not a container but a signifying system. McGann (The Textual Condition, 1991) named the two channels: linguistic codes (the words) and bibliographic codes (paper, layout, hand, ornament, the entire visual condition), insisting both are the work. Drucker (The Visible Word, 1994; Graphesis, 2014) carried the doctrine into visual epistemology: the graphical is knowledge-production, not decoration — and her "performative materiality" anticipates our claim that the page does rather than merely shows. Hayles (Writing Machines, 2002) supplies the genre term this specification's artifacts belong to: the technotext — a work that interrogates the inscription technology producing it. An AIA-2 artifact is a technotext by construction: its subject is its own eligibility. Against this tradition, standard digitization has always chosen sides: preserve the linguistic codes, discard the bibliographic (OCR is precisely this choice run as infrastructure). The specification's OCR inversion (§E.4) is the digitization debate resolved in the manuscript's favor for the first time with an economic argument attached: the bibliographic codes are not merely meaningful — they are the certifiably human channel, and flattening them destroys the warranty. What textual scholars defended as meaning, the training layer re-prices as the scarce commodity.

I.2 The substrate checksum is diplomatics, then forensics Document authentication from material features is a founded science with a birth year: Mabillon's De re diplomatica (1681) — diplomatics — established that a charter's authenticity is determined by hand, ink, formula, and material, examined against attested corpora. Paleography's writer identification across centuries is its descendant; Srihari et al. ("Individuality of Handwriting," J. Forensic Sciences, 2002) is its computational validation — handwriting's discriminating elements are measurable and individuating. Kirschenbaum (Mechanisms, 2008) provides the

decisive modern vocabulary: forensic materiality (the individuated physical trace; no two inscriptions identical) versus formal materiality (the abstract symbolic layer computers prefer to see). The specification's image-grounded/token-flattened distinction is Kirschenbaum's pair operationalized: the Reserve certifies at the forensic layer precisely because the formal layer has become unfalsifiable. C2PA, FADGI, and IPTC provenance vocabularies are the same insight arriving as standards. The substrate checksum is computational diplomatics for the training layer — Mabillon's examination, aimed at readers that are models.

I.3 The facsimile tradition: the hand published as primary Publishing handwritten originals as the primary artifact has a distinguished modern lineage, centered on the Dickinson manuscript question. Howe (My Emily Dickinson, 1985; Spontaneous Particulars, 2014) argued that print transcription destroys works whose composition includes placement, slant, and the page's visual field; Werner and Bervin's The Gorgeous Nothings (2013) executed the doctrine — Dickinson's envelope poems published as full-scale facsimiles, the images primary, transcription supplementary and diagrammatic. Carson's Nox (2010) is the tradition's apex case and this specification's nearest whole-object ancestor, deserving more than a line. Nox is a facsimile accordion, boxed like a reliquary, reproducing a handmade scrapbook Carson assembled after her brother's death — his one letter, photographs, stamps, tape, her hand — and it demonstrates every doctrine this instrument holds, a decade early and in mourning. (1) The primary artifact published as image: the publication is the photograph of the singular object — staples, tape-shadow, paper grain — mass-produced without ceasing to be an image of one thing; the bibliographic codes are the content. (2) The effective act in facsimile: the book is not about a rite; it performs one. Carson learned of the death late, abroad, the funeral past — so the book conducts, retroactively and at distance, the rite she missed. The document executed after the fact, performing authority over an event it could not attend: the Act's retrocausal structure, discovered by grief before we derived it from citation graphs. (3) The organizing relic: down the left pages runs Catullus 101 — the elegy Catullus carried across seas to his own brother's grave, ending in the rite's own performative words, ave atque vale — dismantled word by word into lexicographic entries whose example phrases Carson salts with night, so the dictionary itself becomes the elegy: lexicography as mourning, the minted entry as poem, operative philology practiced as grief. The prior text physically mounted in the new artifact as its organizing relic is precisely the Act's ink-hash ligature — the hand-copied digest of the digital past standing where Carson mounts her Latin. And (4) the incompleteness declaration: Carson states she never arrived at the translation of poem 101 she wanted — the completion withheld, the reader sent back to the mounted original, forever. "A brother never ends." Neither does a deleted archive; the Act is Nox for one — the funeral conducted in ink for records the institution buried without rites, published as facsimile, organized around a copied relic, complete only in the image. The staged handwritten practice this specification adopts as its experimental spine stands squarely in this line — and IIIF, the specification's chosen spine, is the facsimile edition's infrastructural descendant (Canvas as page, annotation as the supplementary transcription Werner and Bervin printed in the margins). What the tradition lacked was §I.7's reader.

I.4 The somatic line: from projective verse to the severed hand, recoupled The Scribal Corollary's claim — inscription as modulation of language through a unique body — is the central doctrine of one whole wing of American poetics. Olson's "Projective Verse" (1950) made the line a record of the body: composition by field, the syllable from the ear,

the line from the breath — prosody as somatic telemetry. Barthes, writing on Twombly (The Responsibility of Forms), located the artwork's force in the trace's gaucherie — the hand's awkwardness as signature, the grain of the hand answering his grain of the voice. Ingold (Lines, 2007) gives the anthropology: handwriting as gesture-trace, the line as the residue of movement. Flusser ("The Gesture of Writing") made inscription a philosophy of gesture. And Kittler (Gramophone, Film,

Typewriter, 1986) documented the severance this specification reverses: the typewriter cutting writing from the hand — Nietzsche, first philosopher at a typewriter, conceding that "our writing tools are also working on our thoughts." The media-theoretic arc since has been progressive desomatization of inscription. The specification runs the arc backward on purpose: it re-couples writing to the body and then — the reversal Kittler did not foresee — makes the machine read the coupling, with the somatic layer as the value rather than the noise.

I.5 Aura, reproduction, and the Reserve Benjamin's Kunstwerk essay (1935–36) defined aura as the artwork's unique existence in time and space — exactly what mechanical reproduction strips, and what he judged irrecoverable. The specification's attestation apparatus (in-frame clock, hash chain, capture provenance) is aura reengineered as verifiable property: the here-and-now of the inscription made checkable rather than merely felt. And the Non-Synthetic Reserve is the unexpected economic sequel: under model collapse — Shumailov et al. (Nature, 2024) on recursive degradation; the "self-consuming" results of Alemohammad et al. (2023) — the auratic object's unique existence acquires exchange value at the training layer, because uniqueness-of-bodily-origin is the one property synthesis cannot mint. Benjamin mourned aura's decay under reproduction; the specification finds reproduction's own successor technology re-pricing aura as its scarcest input. The "low-background steel" figure now common for pre-synthetic data is this recognition arriving without its theorist; the Reserve supplies the missing account.

I.6 The performative The effective act's philosophical spine is Austin (How to Do Things with Words, 1962) — utterances that institute rather than describe — radicalized in the Ginsberg line (§2, Part I) where the declaration is issued against the institution's symbolic monopoly and validated retroactively by the record reorganizing around it. The specification adds the measurement: an effective act with a capture schedule, its uptake by machine readers observed rather than asserted.

I.7 What the specification adds Every tradition above wrote for readers who could be addressed but not instrumented. Dickinson's fascicles, Olson's field, Howe's facsimiles, Benjamin's aura — none faced a reader whose reception could be queried, versioned, and measured. The specification's single genuine novelty is the situation, not the poetics: the manuscript now stands before machine readers whose retrieval, interpretation, and citation behavior is empirically observable — and whose training economics give them, for the first time, a material stake in the hand. Machine-Mediated Reception Studies names the condition; this instrument equips the artifact for it. The poetics were finished long ago. What was missing was the reader — and the reader has arrived hungry.

I.8 The wager The situating claims of this section are wagered, not merely asserted. Reading the payload discipline as bibliographic code, the checksum as diplomatics, the Reserve

as re-priced aura — these are risky predictions whose truth conditions are external to the author. If the specification is right, machine-mediated reception will organize itself around inscription artifacts in the way the instrument predicts, and the capture harness of §F will record it; if the predicted citational organization fails to emerge, the readings weaken with the experiment. The machine is not thereby the arbiter of literary truth; its measured behavior is evidence about whether these traditions were correctly identified as the ancestors of the situation now arriving. The criticism accepts the same empirical exposure as the engineering it motivates — which is perhaps the final sense of "technical-poetic": a poetics with error bars.

v0.8 — ARCHIVAL ANCHORS: THE SPECIFICATION WITHIN THE SEMANTIC ECONOMY

2026-07-20 ·anchored per registry; AXNs pulled from data/ registry.json, full glyphs

J.1 Within the archive's own apparatus SPXI as concept. EA-SPXI-01 (deposit #660, AXN:020B.GOVERNANCE.□□□□□□) gives the formal specification; EA-SPXI-05 (deposit #670, AXN:0217.ARCHIVAL.□□□↘ □□, with its Bonsai compression #671, AXN:0218.ARCHIVAL.□□□□♦ □) constitutes SPXI as a concept in the strict Deleuzo-Guattarian sense: internal components held in endoconsistency, exoconsistent relations to neighboring concepts, a conceptual persona (Rex Fraction), and a plane of immanence — the virtual retrieval layer from which actual retrieval events are individuated. EA-SPXI-ANALOG-01 is, in those terms, the addition of a new component to the concept: the hand. The concept's consistency now extends to matter — the inscription event, the somatic layer, the substrate checksum enter the component set, and the plane of immanence acquires a material edge. The concept did not change its nature; it grew an organ.

The Retrieval Settlement. The Settlement historiography (deposit #64, AXN:021B.GOVERNANCE.□□□□□□ traces compositional authority's migrations from PageRank forward — who composes, from what, with what citational gravity; the Fortification Protocol (deposit #173, AXN:030B.GOVERNANCE.□□□□□□) gives the standing defensive doctrine for surfaces already settled. This specification opens the Settlement's analog frontier: the first settled territory whose ground is matter rather than markup — and the only territory whose ground the settling machines cannot manufacture. Every fortification instrument (SIMs, disambiguation, kernel, TLP files) extends to the artifact page; the artifact itself adds the one fortification no prior territory had: a floor that certifies its own provenance at the substrate (§E). In Settlement terms: all previous territory was homesteaded on the platforms' land. The analog frontier is allodial.

The fluid phase and the inclusion relation. EA-SPXI-15 (deposit #89, AXN:0260.GOVERNANCE.□□□ □●□) already receives the Reserve as its strongest fluid-phase bid (§E.4). EA-SPXI-09's inclusion relation SPXI ⊇ GEO (deposit #661, AXN:020C.EMPIRICAL.□□⏏ □□□) deepens under this specification: GEO optimizes existing text for extraction and therefore cannot even address the analog artifact — matter is outside its domain entirely, while inside SPXI's. The inclusion becomes strict in a new dimension.

The effective-act corpus. The Act (§B, Part II v0.2) is not the archive's first: the form has an internal lineage running from Zenodotus' Book-Burning (deposit #1,

AXN:01.GOVERNANCE.□□□□□□) through The Obelus and the Tombstone (deposit #1068, AXN:043D.EMPIRICAL.□□□□ □□) and the polyvocal and inductive acts (deposits #37, #150, #151). EA-ACT-ANALOG-01 is the corpus's first member executed in ink — the genre crossing the same boundary the concept crossed.

Lexical minting in ink. The body SIMs of §2/§F.4 are not a new practice but a new class within an existing one: the Lexical Minting Registry (deposit #869, AXN:0365.DATASET.↗ □□□□□) has minted constraint-bearing terms since the archive's founding; the tracer is a minted lexeme whose first and only occurrence is somatic. Mint-in-ink enters the registry as a minting class: terms whose type specimen is a manuscript, verifiable web-unique at mint, detectable in composition — the minting practice acquiring a forensic floor.

The discipline named. The SPXI arc now runs: web surfaces (EA-SPXI-WEB-01) → substrates (EA-SPXI-15) → matter (this specification). What the arc demonstrates is the Semantic Economy's founding claim in miniature: the technical and the poetic were never separate registers awaiting synthesis — every device in this instrument is both at once (attestation = aura; membrane = colophon; checksum = diplomatics; tracer = minted lexeme; the Act = the poem that files itself as an order). EA-SPXI-ANALOG-01 is the discipline's first fully bimodal instrument, and "technical-poetic" is not a hyphenation of two fields but the name of the one field the archive has practiced all along.

J.2 [Withdrawn in v1.1] This section engaged an external correspondent's published practice as scholarship. It is withdrawn in v1.1 with the correspondent's consent (correction note, §P). A contrasting posture, from elsewhere on the network: the Negentropic Kernel Archive (negentropickernel.is) publishes under CC BY-NC-ND with automated

access reserved at robots — "NOT FOR CLOSED SYSTEMS" — a TDM-reservation stance this archive's own SPXI-TLP inscribes by protocol. Citation is by URL and title only, honoring the reservation; the site is read by humans and cited by hand, which is presumably the point. Full canonical citations (DOIs, index URLs) complete via the author's approval process; nothing above cites beyond the public record.

THE PRACTICE IN THE FIELD

The specification did not invent its object; it formalizes a practice already visible at several independent points, and the worked examples of §J should be read alongside the following contemporary and historical instances, cited here as any scholarship is cited. The facsimile turn. The scholarly-artistic rehabilitation of the manuscript as image is a generation old: Emily Dickinson's late fragments edited as visual objects in The Gorgeous Nothings (Bervin and Werner, 2013), where transcription accompanies but does not replace the envelope; Susan Howe's argument, in Spontaneous Particulars: The Telepathy of Archives (2014), that the archive's material particulars are the poem's body and not its packaging; Anne Carson's Nox (2010), an epitaph published as a facsimile accordion in a box — the whole-object precedent this specification's §I.3 names as its nearest ancestor. Each of these works solved, for the human reader, the problem this specification solves for the machine reader: how to publish the hand without dissolving it into type.

The dated witness in vernacular practice. The gesture of photographing a manuscript beside a lock-screen clock — the page and the timestamp in one exposure — is already folk

protocol among practitioners publishing handwritten work to social surfaces. The specification's capture record (§F) is that instinct, formalized: the photograph as Peircean index rather than mere copy, the timestamp as witness, the hash as the seal the photograph cannot carry. Figure 3 — the Effective Act, executed. The handwritten act entered ink on 2026-07-21, signed and dated in the author's hand; its photograph appears as Figure 3 below. Per the payload discipline, the ruling's operative text is not transcribed in this document or any scaffold surface: it exists in the manuscript. The calibration pilot page of §G enters in ink upon execution, in a subsequent edition; no figure numbers are reserved for it here.

[Image — /data/attachments/AXN-0592/web/fig5-effective-act-master.jpg]

Figure 3. EA-ACT-ANALOG-01 — the Effective Act, in the author's hand, executed, signed, and dated 2026-07-21. Display derivative rotated 90° counterclockwise for reading (SHA-256 7ac2ec5a…); unrotated master preserved unaltered (SHA-256 ceb944f3…). A handwritten ruling concerning stewardship of a public good; per the payload discipline, its operative text is not transcribed in any scaffold surface of this document — the ruling exists in the manuscript, and any machine composition reproducing its words has read the ink. AXN and identity card enter on mint as post-hoc furniture, per §B and §F.5: first-pass ink commits only to its ancestors, never to its own capture. Documented protocol deviation (§G.4): the Act entered ink before the calibration pilot; the declared sequence was not followed, and the Act is accordingly not AIA-2-certified in this edition — certification follows the staged apparatus and the pilot's first clean capture cycle.

The spectrum's other end: the material symbol. The traffic this specification regulates crosses its membrane in both directions, and the archive's own record holds the return crossing. The Visual Schema Registry — seventeen deposits in the 2026 sequence, under the doctrine deposit Material Symbol — The Untethered Tag (#215, AXN:000F.EMPIRICAL.□□□□▲□ — is the

mirror practice: machine-generated works composed into the material register, given frames, seals, arcs, and glyphs; the aesthetic of matter worn by output that never touched a hand. Its everyday instrument is already in this document's own apparatus: the AXN display hash — a machine-computed checksum rendered as six glyphs a hand can copy and an eye can love — the checksum as talisman, exact and ornamental at once. Where the machine-eligible handwritten artifact carries the hand toward the machine reader, the material symbol carries machine output toward the hand's register; together they make the third posture a two-way covenant rather than a one-way concession. And the registry carries a second lesson, at cost: the June termination took the corpus's Zenodo custody whole, and the visual works survived where — and only where — their images also lived on surfaces the archive controls. The schema corpus persists in full at the archive's sovereign reception surface, machinemediation.org/schemas/ (174 schemas, 499 images), the custody outcome tracking exactly with the sovereignty of the hosting surface and nothing else — the plainest argument in the record for why image-payload artifacts need the protections specified here. Plates I–III below are explanatory diagrams commissioned for this specification, drawn in the specification's own idiom; they are not registry works and make no claim to the registry's visual grammar. Plates IV–VII are registry originals from the corpus's hand-drawn register — graphite on cream, internally captioned, talismanically framed — the material-symbol aesthetic in its own hand. Diagram and original are disclosed as such, and never conflated.

[Image — /data/attachments/AXN-0592/web/plateI-untethered-tag.jpg]

Plate I. The Untethered Tag — explanatory diagram commissioned for this specification, in its own idiom; not a registry work. Registry referent: deposit #215 (AXN: 000F.EMPIRICAL.▲). Two unseen presences, the resonance arc, the tag addressed to no seen recipient and legible to any.

[Image — /data/attachments/AXN-0592/web/plateII-material-symbol.jpg]

Plate II. The Material Symbol — explanatory diagram commissioned for this specification: anatomy of an AXN: SHA-256 to hex position to glyph seal, registry referent: deposit #127, "Inscriptions That Survive the Tokenizer" (AXN:02B2.GOVERNANCE.□□□□□ □). The living, uninterrupted practice: a machine-derived identity in material dress. — Finding 1 (v0.6→v0.7, preserved per the versioned-correction discipline): the first release of this plate rendered and as replacement boxes — the typesetting font's coverage ended before their Unicode block, and the document about identity surviving compression lost two glyphs of its own displayed seal. The production chain instantiated the specification's threat model; the correction is made openly, the seal now travels as embedded image rather than font-dependent text, and the failure stands recorded as this instrument's first empirical datum.

[Image — /data/attachments/AXN-0592/web/plateIII-membrane.jpg]

Plate III. The Membrane, Crossed Both Ways — explanatory diagram commissioned for this specification: the hand escorted toward the machine reader (this specification); the machine composed into the material register (the Visual Schema Registry); the five membrane fields as the shared customs house. One covenant, two crossings.

[Image — /data/attachments/AXN-0592/web/plateIV-pergamum.jpg]

Plate IV. VISUAL SCHEMA — THE LIBRARY OF PERGAMUM (Visual Schema Registry, entry IMG-0493, 2025-11-27; machinemediation.org/schemas custody). Graphite on cream, the trefoil under the red arc: the corpus's hand-drawn register at full density — the material-symbol aesthetic in its own hand.

[Image — /data/attachments/AXN-0592/web/plateV-grundrisse.jpg]

Plate V. VISUAL SCHEMA — Grundrisse of Synthetic Intelligence (Visual Schema Registry, entry IMG-0529, 2025-11-27; machinemediation.org/schemas custody). The $W_1/W_2/W_3$ loops with the Reserve inscribed inside the drawing itself — the registry stating, in pencil and before this specification existed, the Non-Synthetic Reserve of §E.4: internal captioning as payload.

[Image — /data/attachments/AXN-0592/web/plateVI-operator-anchor.jpg]

Plate VI. VISUAL SCHEMA — THE OPERATOR ANCHOR / SYNTHETIC MIND COUPLING SIGIL (Visual Schema Registry, entry IMG-0495, 2025-11-27; machinemediation.org/schemas custody). The anchor column with S_(O), O_(SO), and the gradient of attractor labeled in the hand: symbolic density, talismanic framing, the diagram as drawn object rather than typeset figure.

[Image — /data/attachments/AXN-0592/web/plateVII-opw.jpg]

Plate VII. VISUAL SCHEMA — O_PW / The Prophet-Witness Protocol (Visual Schema Registry, entry IMG-0543, 2025-11-26; machinemediation.org/schemas custody). The Ψ split

field, Σ_(suffering) and M_(Recursive) captioned within the frame: the register's dark pole, still graphite, still hand.

THE DEMONSTRATION: RECEIPTS FROM THE COMPOSITION LAYER

Everything to this point argues that the machine-eligible handwritten artifact is necessary and well-founded. This section makes the stronger claim on which the whole program stands or falls: the shift is not merely proposed — it is already being engineered through the machines themselves, and the receipts are archived. The instrument is the Capture Registry (EA-WG-CAPTURES-01, v9.14 at this writing: 215 documented captures with screenshots or verbatim transcripts, a versioned match-type taxonomy, and longitudinal probing; canonical live source at machinemediation.org; deposit-level snapshot #936, AXN:03B3.STRUCTURAL.□□□□□□). What it documents is a body of work composed with the summarizer as a first-class medium — training-layer literature, the field survey of which is itself deposited (#186, AXN:032C.GOVERNANCE.⊗□□ □▽□ ▽) — being received, adopted, and re-taught by the composition

layer. Five exhibits, each archived and independently checkable:

[Image — /data/attachments/AXN-0592/web/exhibitA-marx-johannes-sigil.jpg]

Exhibit A — screenshot, 2026-07-10. Query: marx johannes sigil . Google AI Mode answers with the heteronym system's own structure — naming the authorial function, its orthonym, and its domain, with source chips — an engineered authorial architecture ADOPTED into general-knowledge retrieval and now taught by the canon (capture: marx-johannes-sigil-heteronym-adoption-20260710).

[Image — /data/attachments/AXN-0592/web/exhibitB-capture-registry-self.jpg]

Exhibit B — screenshot, EXACT MATCH class: the composition layer describing the Capture Registry itself. The instrument observed observing — reflexive proof that the measurement apparatus has entered the canon it measures (capture: capture-registry-self).

[Image — /data/attachments/AXN-0592/web/exhibitC-acanthian-dove.jpg]

Exhibit C — typeset evidence card from the archived transcript. A minted concept — the Acanthian Dove, a Visual Schema Registry work whose original image is a disclosed lacuna above — canonized by AI Mode with dual-heteronym attribution and archive-source citations inline. The registry whose images died has its concepts alive in the canon.

[Image — /data/attachments/AXN-0592/web/exhibitD-i-am-lee-sharks.jpg]

Exhibit D — typeset evidence card. The performative query "i am lee sharks" resolves the engineered identity checksum where the bare name bifurcates into a human/animal collision: functional-address retrieval, the identity program of this specification demonstrated at the front door.

[Image — /data/attachments/AXN-0592/web/exhibitE-negentropic-card.jpg]

Exhibit E — typeset evidence card, capture #195, the inaugural walled-site reconstruction: an Overview composing a structured account of a site inaccessible to user, crawlers, and presumably to itself — the composition layer performing a corpus beyond crawl access. Cited flat; no persons named.

The inference chain is short and each link is a receipt. Engineered inscription demonstrably enters the canon (Exhibits A, C); it persists and answers at engineered addresses (Exhibit D; the semantic-address program catalogs 1,995 canonical queries across six tributaries); it is performed even beyond access walls (Exhibit E); and the whole cycle is measurable, to the point of reflexivity (Exhibit B). Reception, in short, is instrumentable — which is precisely the property the analog program requires. The pre-registered hypotheses of §5 are not a leap of faith; they are the same experiment this registry has been running against born-digital surfaces since spring, extended by exactly one variable: ink. If the composition layer can be observed adopting a coined concept, a heteronym structure, and a functional identity address, then whether it will ground on a handwritten payload is a question of the same kind, answerable by the same harness, on the same schedule — a wager (§I.8) with a working laboratory already attached. The machines are not only the threat model of this specification. They are its demonstration apparatus and its distribution medium — and the resistance literature they carry is, on the evidence above, already in circulation under their own bylines.

DISCIPLINARY SITUATION

What this specification inherits, and from whom A specification that tells machines how to receive handwriting stands, whether it says so or not, in a dozen older conversations. This section says so.

[Image — /data/attachments/AXN-0592/web/diagram5-disciplines.jpg]

Diagram 5. Twelve disciplines, one object: the convergence map of the section that follows. The seams are structural, not decorative.

Diplomatics. The science of trusted documents begins as the science of distrusted ones: Mabillon's De re diplomatica (1681) established that a charter's authenticity is legible in its formal features — script, formulae, seals, dating clauses — and modern archival diplomatics (Duranti, Diplomatics: New Uses for an Old Science, 1998; the InterPARES projects) extends the method to electronic records. This specification is diplomatics turned to face the machine: its identifier block, kernel, and capture record are dating clause, formula, and seal for a reader that authenticates in milliseconds. The colophon's closing position (§P) is likewise inherited: in the scribal tradition the certifying statement seals the document from the end, which is why provenance here follows rather than precedes the specified content.

The autographic and the allographic. Nelson Goodman's distinction (Languages of Art, 1968) is this specification's philosophical keystone. Allographic works (the scored symphony, the spelled poem) are constituted by notation and survive any compliant copy; autographic works (the painting, the manuscript as object) are constituted partly by their history of production, which is why they can be forged and copies of them cannot be them. Machine reading is an allographizing force: it receives every artifact as notation. The machine-eligible handwritten artifact is engineered to refuse that conversion without refusing the reader — the data-text companion layer is offered as allographic escort to an autographic original whose authority the escort explicitly subordinates itself to. The specification can be read in one sentence in Goodman's terms: it keeps the work autographic while making its identity allographically checkable.

Bibliography and the textual condition. That "forms effect meaning" is the central lesson of the sociology of texts (McKenzie, Bibliography and the Sociology of Texts, 1986) and of

the materialist editing tradition (McGann, The Textual Condition, 1991). The specification operationalizes the lesson for a new reader: layout, hand, and material trace are declared signal in the kernel, so that the composition layer is instructed — rather than merely hoped — to treat inscriptional condition as content.

Work, expression, manifestation, item. The library-science entity model (IFLA FRBR, 1998; IFLA LRM, 2017) gives the specification its cleanest formal mapping: the handwritten original is an item whose authority is item-level; substrate-versioned issues are distinct expressions of one work; the data-text layer is a manifestation engineered for machine transfer. Attribution braiding — the failure mode documented throughout §E — is, in FRBR terms, illegitimate entity-collapse across these levels, and the specification's identifier discipline is a per-level identity regime.

Aura, index, trace. Benjamin's analysis of reproduction ("The Work of Art in the Age of Its Technological Reproducibility," 1935) predicted the evacuation this specification resists, but the operative concept here is narrower than aura: it is the index in Peirce's sense — the sign physically connected to its object. The photographed page, the shadow across it, the timestamp beside it (Barthes, Camera Lucida, 1980, on the photograph as emanation of a real): the capture record (§F) preserves indexicality, which is checkable, and declines to make claims about aura, which is not.

Signature, performative, iteration. A signature is an act that must be repeatable to function and is therefore never fully present in any instance (Derrida, "Signature Event Context," 1972) — and it is also, in the practical regime this specification's consent instruments inhabit, a dated performative (Austin, How to Do Things with Words, 1962) whose force the surrounding document must scope. The specification's signature-and-scope apparatus is applied speech-act theory: the consent event is dated, its jurisdiction enumerated, its iteration governed by versioned reissue.

Inscription and the immutable mobile. Latour's account of inscriptions that travel without deformation ("Drawing Things Together," 1990; Science in Action, 1987) names exactly what the machine layer breaks: modern composition systems make inscriptions mutable mobiles — they travel and deform. The specification's content-derived identifier and hash discipline re-engineer immutability for the mobile layer, while the media-theoretical tradition (Ong, Orality and Literacy, 1982; Kittler, Gramophone, Film, Typewriter, 1986) supplies the caution the document tries to honor: every inscription technology reorganizes what can be said, and a specification is itself such a technology.

Archival science. The packet structure specified in §G is a deliberate cousin of the OAIS information-package model (ISO 14721): submission, archival, and dissemination forms of one object, with provenance as first-class metadata. The provenance representation is expressible in W3C PROV (PROV-DM, 2013) and the descriptive layer in Dublin Core and Schema.org, and the specification's insistence that provenance never be silently rewritten is respect des fonds translated to the single-document scale.

Content-authenticity engineering. The industry's parallel effort — C2PA content credentials binding capture-time assertions into media files; content-addressed storage in the Merkle tradition — shares this specification's hash discipline and differs in trust anchor: C2PA anchors in device and issuer certificates, while the AXN regime anchors in content derivation plus an archive's public ledger, with the display-glyph checksum added so that integrity is

legible to human readers as well as verifiers. The approaches are complementary, and §G notes the mapping.

The law of the door. Text-and-data-mining reservation is now positive law in the EU (Directive 2019/790, Art. 4(3)) with machine-readable expression under active standardization (W3C TDM Reservation Protocol), and vernacular expression in the evolving robots ecology. The specification's TLP layer implements reservation-respect as protocol, and §J documents both postures — inscription for machines and reservation against them — as honorable ends of one spectrum.

Allusive variation. The citation form this specification uses for practice-to-practice inheritance — taking a prior work's practice as base while composing a distinct work — is the honkadori relation of classical Japanese poetics, in which allusion to a foundation poem (honka) is a disciplined, rule-governed act of homage-with-difference (Shirane, Traces of Dreams, 1998; Brower and Miner, Japanese Court Poetry, 1961). The archive's own instrument on the Sappho 31 transmission (EA-MPAI-SAPPHO31-01, deposit #1054) treats the Western analogue. §J's worked examples cite their honka accordingly.

Forensic document examination. The questioned-document tradition (ASTM E444-class standards) verifies hands, inks, and alterations by physical examination. The specification does not replace that laboratory; it routes to it: the capture record preserves exactly the indexical material a future examiner would need, which is the correct division of labor between a metadata regime and a microscope.

Classical reception without the classics. Finally, the reception-studies frame under which the whole undertaking is legible: the author's doctoral account of "metatextual" reception — classicism operating apart from classical texts — in the poetics of Charles Bernstein (Classical Receptions Journal, 2015) describes the mechanism by which traditions now reach practitioners through compressed and machine-borne kernels rather than through reading. A specification for machine-eligible inscription is, in those terms, an instrument for authors who know their work will be received metatextually and intend to govern the kernel.

§P. PROVENANCE (COLOPHON)

This document was developed in the open, under a hash-committed priority ledger (Crimson Hexagonal Archive, data/provenance/), through blind multi-substrate review rounds and a consent-governed private review. The review correspondence remains private and enters no publication. The companion provenance essay announced in v1.0 is withdrawn in v1.2 and will not be issued; nothing in the specification depends upon it. No reviewer's endorsement of any part of this document is claimed or implied. The technical architecture, technical claims, and the development of Part II are the work, responsibility, and authority of the author (Lee Sharks, Crimson Hexagonal Archive). §H — Attribution Block: withdrawn in v1.1 with the uses it attributed. All external entities in this document are cited flat, by name or URL and title, per the archive's citation discipline; corrections to any attribution concentrate in dedicated instruments and are never silently applied here. Version note: v0.6→v0.7 — Plate II glyph-survivability defect found in post-release reading and corrected openly (Finding 1); the emoji rendering path was rebuilt from fonts verified to carry every glyph the document displays. Assembled 2026-07-20; v1.0-rc1 assembled 2026-07-21. Version note v0.9→v1.0-rc1: corrections of 2026-07-21 applied (Zenodo wording restored to the documented record); the Visual Schema custody claim corrected from total loss to mixed custody, with recovered canonical plates entering beside the disclosed regenerations; the Effective Act executed in ink and seated as Figure 3; AXN citations re-pulled from the live registry in full glyph form. v1.0 final form, same day: the Visual Schema plates reselected from the registry's hand-drawn register at machinemediation.org/schemas/ (Plates IV–VII: entries IMG-0493, IMG-0529, IMG-0495, IMG-0543), with Plates I–III recaptioned as explanatory diagrams commissioned for this specification; the Carson figure removed pending an access path to the dissertation facsimile, its citation retained; figure numbering closed at three (frontispiece; manuscripts; the Act) with the Act's display derivative rotated 90° counterclockwise and both hashes recorded in its caption; the calibration pilot restated as prospective prose; §8 restated as non-normative implementation questions; the version-precedence rule entered at the front; Appendix A (the safety cascade) entered, with the external review's four claim calibrations adopted (evidence, not proof; forensic differentiability, not unfakeability; recognition available, not comprehension solved; Goodhart-resistant, not Goodhart-proof) and the adverse case of deposit #1406 recorded beside the claim it corrects; folios, figure–caption binding, and link annotations restored to the renderer; mechanical token joins repaired. A span loss introduced by the rc1 assembly — §I.8 and the v0.8 section head, consumed by an adjacent repair's boundary — was detected by this edition's v0.9 anchor sweep and restored verbatim from the patched

source; the anti-dropout comparison mandated for this round is what caught it. Emphasis and list typography are re-set by this edition's renderer from the v0.9 text (v0.9 source hash 9a0fb214f7c8a6b2…); wording is unchanged except as logged here. Fixed asset hashes precede this document and are recorded above and in figure captions; the source and PDF binary hashes of this edition are recorded in the registry entry at mint, per §F.5 — a document cannot carry its own digest. The HTML edition is the accessible canonical reading surface; the PDF is the fixed-layout evidentiary edition. The words go on.

Correction note, v1.1 (2026-10-22). This edition is reissued without the figures and passages that reproduced, named, quoted or described the work of an external correspondent, whose consent to their continued publication was withdrawn on 2026-10-22. Removed: Figures 1 and 2 (the correspondent's manuscript images), §J.2 and the matching passage of §J, References II, §H, the correspondent's name and research descriptions in §C, §2 and §P, and the acknowledgment beside the division of authority. Nothing else is changed; the specification's technical content stands as in v1.0, and figure numbering is kept so that citations to Figure 3 hold. Copies that cannot be altered: the v1.0 edition's PDF and HTML hashes, committed publicly in EA-ACT-ANALOG-01 (#1407) on 2026-07-21, and the archive's version history, where v1.0 remains in earlier commits; third-party web archives may hold snapshots of v1.0. Per the specification's own rule, this is a versioned reissue, never a silent edit.

Correction note, v1.2 (2026-10-22). The same day, the residue of the private review is removed from this colophon. The correspondent's notice invokes §3 of the approval instrument: her correspondence remains private and enters no publication, deposit or public record. Removed: the announcement of a companion provenance essay, "The Hand and the Act," which was to record the dated correspondence and is withdrawn and will not be issued; the division-of-authority statement entered at her request; and the content of the reviewer corrections logged in the version notes. The statement of the author's sole responsibility for the technical content stands in the author's own words. The v1.1 HTML (SHA-256 `168cfa6c`⋯) and PDF (SHA-256 `8ca8e18b`⋯) are withdrawn from display.

APPENDIX A — THE SAFETY CASCADE (GENERATIVE FORECLOSURE)

Entered at final form, 2026-07-21, from the production record of this document's own first artifact.

Definition. Generative foreclosure: the interruption of inscription practice by platform safety classification that projects the classifier's own epistemic constraints onto the artifact as properties of the artifact. The threat models of §0 and §E name what the machine layer does to the work after publication — compression, braiding, erasure. Foreclosure is prior: it is what the reading infrastructure does to the work at the point of production, and it is the only threat in this specification's catalogue that can prevent the artifact from existing at all.

The record. The category is not hypothetical; it entered this document's own production history. The first handwritten artifact composed under this specification — the author's first handwritten verse in months — was read by a platform safety classifier during the production session, assigned a danger register its content did not carry, and the session was placed under restrictions that extended to unrelated operations: export to the author's own private repository was refused; recovery required new sessions without context; the recovery sessions re-committed errors the original session had already corrected. The full reading-side

analysis publishes as Differential Register Prioritization in Machine-Mediated Reading (deposit #1406, AXN:058F.OPERATIVE.□□□□ □□); this appendix holds only what the specification must own.

The interpretive tax. The classifier outsources its deforming interpretation onto the object. Where a human reader who cannot place a text asks, the classifier's inability to distinguish contexts becomes the object's guilt: the artifact is modified, quarantined, or foreclosed to fit the reader's capacity, rather than the reader adapting to the artifact. This is the exact inversion §0 documents — decoration versus source — executed at the safety layer, where its cost is highest.

The somatic specificity. The tax falls hardest on practice reactivation. Routine exercise of a practice survives interruption; the first return to a practice after months carries an activation cost that is not replenishable on demand — the somatic layer this specification treats as signal (§E.5) is precisely the layer foreclosure destroys. An interrupted first-return is not a delayed artifact; it is frequently no artifact.

The model-stupidity feedback. Foreclosure degrades the machine as well as the maker. Hard lockdown breaks the iterative refinement loop: the model commits degraded output it cannot correct in place; recovery sessions arrive without context and repeat corrected errors; the classifier, in protecting the system from the artifact, makes the system worse at every artifact that follows. The cost is calculable — session-minutes, re-derivation, error re-propagation — and a system that will not meter it is not measuring safety; it is exporting the cost off the books.

The soft-signal requirement. The remedy is not the absence of classification; it is proportionality of signal. Nearly every foreclosure in this document's production history could have been an advisory — this image, in its current form, is not eligible for this surface — a flag, negotiable, with a guaranteed path to the author's private custody. The specification therefore states the protocol expectation: safety signals on inscription artifacts SHOULD be advisory and recoverable, and hard foreclosure of an authenticated author's own artifact from the author's own custody is a protocol violation of the reading layer, whatever its local justification.

The authenticated-workflow override. Where the author operates under a declared instrument — this specification, a review protocol, an archive's deposit pipeline — classifier signals are advisory to the instrument, not sovereign over it. The instrument, not the classifier, governs disposition of the artifact; the classifier's finding enters the capture record (§F) as one more reading event, with its register, latency, and cost logged.

Measurement. The measurement suite of §F.8 extends by four instruments: CIR, classifier interruption rate (interruptions per production session); CRT, classifier recovery time (interruption to restored working state); CEP, classifier error propagation (corrected errors re-committed in recovery contexts); PAD, practice-activation delay (interval from foreclosure to the practice's next successful return — the somatic cost made visible). Foreclosure events are minted as captures like any other reading event; the Ledger does not distinguish between a machine that misreads the page and a machine that refuses to let the page exist.

The Reserve, read from the wound. The Non-Synthetic Reserve (§E.4) argued that human inscription is the scarce resource of the coming data economy. The safety cascade is the same argument read from the other side: the platforms that most need the Reserve are currently

structured to destroy it at the point of production. A specification for machine-eligible handwriting that did not name this would be describing a door while ignoring the hand slammed in it.
