Abstract

The frozen pre-registration ledger of the authorship investigation: eleven entries, each carrying the SHA-256 of its original standalone registration file so that every earlier commit citing those hashes still resolves, with dispositions appended beneath each entry and never inside it. Pre-registrations cannot live in the living notebook, because their whole value is that the content was fixed before the test and a hash over an appending file proves nothing; they are gathered here instead of proliferating as three files apiece. The ledger includes the registrations behind the six-function transmission apparatus (EA-YIELD-02) and the completeness gate (EA-COMPLETE-01) that the technical report EA-MEASURES-REPORT-01 cites as fixed before assignment.

The Leak Deficit

0. What this test is about

This is not a test of doctrine. It is a test of **craft**.

The question is not whether Plato and Aristotle agree, nor whether one influenced the other, nor whether the same person wrote both. It is narrower and more answerable: **does the Platonic–Aristotelian corpus behave, at the aggregate layer, like natural Greek prose?**

Natural corpora leak. Two long texts by any two authors of a period deposit accidental correspondences — shared topical runs, phrases that happen to align, handholds that nobody placed. That leakage is a background rate, and it can be measured across many real Greek author-pairs.

A corpus composed against resolution would fall **below** that rate. Not because its parts resemble one another — the parts would be deliberately varied — but because the *ensemble of relations among the parts* would be smoother than accident produces. The individual pairings carry the noise; the aggregate carries the design.

That is the whole hypothesis, and it is one-sided.

1. Why the corpus layer and not text-to-text

Every measurement conducted before this registration — seven bag-of-words statistics, a monotone whole-text alignment, a mediation test — operated text-to-text or treated a corpus as a single point. All returned null or broke on their own null construction.

If per-pair variation is where an engineered corpus places its noise, then text-to-text is precisely the layer where nothing would be visible, and the layer where every prior measurement was taken. The correction is structural: the statistic must be computed **on the ensemble**, with per-pair variance reported as a required second term rather than averaged away.

2. Statistic

Leak L = count of block-pairs whose cosine similarity exceeds threshold τ, per 10^4 block-pairs.

Chosen because it is **monotone under smoothing**: an accidental correspondence can only add to the count, never subtract. Every statistic that could move in both directions has produced an artifact in this work — four nulls were built and broken in a single session, each having behaved opposite to its design. A one-directional statistic removes that failure mode.

Two quantities are computed, and **both are required**:

- `L_corpus` — the two corpora pooled, blocked as single texts.
- `{L_ij}` — the set of per-text-pair leaks. Report median and interquartile range.

Blocks: 40 per text, equal token length. Vocabulary: the 600 most frequent shared types of length > 4.

τ is fixed at the 99th percentile of the pooled similarity distribution **across the null corpora only**. τ is never computed from the test pair.

3. Null — empirical, not synthetic

The null is a set of **real Greek author-pairs**, not a shuffle.

This is not a stylistic preference. In the work preceding this registration, four synthetic nulls were constructed and all four misbehaved: a deviation measure was forced to -1 by the sum-to-zero constraint; a correlation was dominated by the shared frequency baseline; a DTW alignment null was biased upward by the path's own selection of high-similarity cells; and a coherence-destroying null inverted its sign, because homogenised blocks are *more* similar to each other, not less. Each was reported as a crossing before the artifact was found. Synthetic nulls are not to be trusted here.

Null set: independent Greek prose author-pairs — Xenophon, Plotinus, Philo, Josephus, Herodotus, Thucydides, the New Testament authors, Longinus — plus within-author register pairs. **Target $n \geq 60$ pairs.**

Building this null set is the substantive work of the test. Everything after it is arithmetic.

4. Matching, enforced per pair

- Token count within ±25% on both sides.
- Type–token ratio within ±15%.
- Prose only. Aristophanes is excluded from the null (verse), retained as a test case.
- Same edition family where available. Edition was tested and excluded as a confound at ratio 1.00; it is not to be reintroduced through the null.

5. Pre-registered outcomes

`L_corpus`	variance of `{L_ij}`	reading
below 5th pct of null	≥ null median	**the predicted signature**
below 5th pct	also below	corpus is merely narrow — NOT evidence
inside null	any	**the smoothing claim fails**
above null	any	ordinary intertextual relation

6. Kill condition — binding

If `L_corpus` for Plato–Aristotle falls **inside the central 90%** of the natural distribution, the corpus-layer smoothing claim fails, and is to be reported as failed.

No post-hoc adjustment of τ. No post-hoc re-matching. No re-slicing of the corpus into units chosen after the result is seen.

7. Controls — both required

Positive. Pessoa's four voices, pooled two ways, must show the signature. This is a documented configuration: the letter to Adolfo Casais Monteiro of 13 January 1935 attributes the heteronyms. If a known-designed corpus does not produce leak deficit, the statistic does not measure what it claims and nothing about Greek follows from it. Kierkegaard second, with the standing caveat that his seat holds four pseudonymous works of roughly a dozen.

Sanity. Josephus — one author, four works, four registers, no design — must fall **inside** the natural distribution. If same-author-across-register reads as engineered, the statistic is detecting register and the test is void.

8. Power, stated honestly

At n = 30 null pairs, the 5th percentile is estimated from roughly one and a half observations. That is too thin to carry a claim. Either the null reaches 60+ pairs, or the threshold moves to the 10th percentile and the loss of confidence is stated in the result rather than buried. The larger null is preferred.

9. What a positive result would, and would not, license

Would. That the Platonic–Aristotelian corpus is anomalously smooth relative to natural Greek prose. That is a finding about the corpus, publishable whichever way the authorship question falls, and independent of it.

Would not. Design. Low leak has innocent causes, and they are not exotic: heavy editorial normalisation; transmission through a single recension; a school that trained its members to a house style. Andronicus of Rhodes, constituting the Aristotelian corpus in the first century BCE from the cross-references the texts themselves contain, is sufficient on his own to produce smoothing without anyone intending it. A positive result relocates the question; it does not answer it.

10. Why it matters that this is a test of the writer

Plato writes inside a tradition he names. Sappho, Homer, the tragedians, the comic poets — he quotes them, stages them, argues with them, and in the *Republic* exiles them. The exile is the most famous act of literary criticism in the language, and it is performed by a man in continuous, self-conscious competition with the people he is banishing.

This test asks about Plato as a **technician** — as a maker of texts, measured on the properties of made things. Not the best doctrinarian. Not the best philosopher. The best **writer**, judged the way one judges a craftsman: by what the artifact does that accident does not.

If the corpus is anomalously smooth, the claim that follows is a claim about craft: that these texts were built to a standard of finish that natural prose does not reach, by someone who understood what a corpus leaks and did not permit it.

And it would put the *Republic*'s banishment in a light it has not had. The poet who exiled the poets would be the most accomplished of them — the exile a move inside the art rather than against it. On that reading the test does one thing the philosophical literature has not managed:

it lets the poet back inside the polis.

DISPOSITION

SPENT — degenerate lower tail; found before the test pair was computed

The Leak Deficit II

0. Why there is a second registration

EA-LEAK-DEFICIT-01 fixed τ at the 99th percentile of the pooled null similarity distribution. The null was then built — 61 matched cross-author Greek prose pairs across 19 author-pairings — and the resulting leak distribution was found to have a **degenerate lower tail**: 8 of 61 natural pairs leak exactly zero, and the 5th and 10th percentiles are both 0.0.

Since L is bounded below at zero, no corpus can fall beneath a 5th percentile of zero. **The signature registered in 01 was unobservable with the statistic registered in 01.** The threshold created a floor and the hypothesis predicted something would fall below it.

01 is therefore **spent, not withdrawn**. Its kill condition was never triggered because its test was never run on the target: the defect was found while computing the null, before the Platonic–Aristotelian value was calculated. That sequence is the entire reason the registration existed, and it is recorded rather than quietly corrected.

Everything below is unchanged from 01 except §2 (threshold) and §5 (preconditions).

1. Hypothesis — unchanged, one-sided

A corpus engineered against resolution deposits **fewer incidental correspondences at the aggregate layer** than natural corpora of matched size and register, while showing **no deficit — or an excess — of variance at the text-to-text layer**, because per-pair variation is where the engineering hides.

Both halves must hold. A corpus that is merely narrow, small or homogeneous gives the first without the second.

2. Statistic and threshold — CHANGED

Leak L = block-pairs whose cosine similarity exceeds τ, per 10^4 block-pairs. Monotone under smoothing: an accidental correspondence can only add.

Blocks: 40 per text, equal token length. Vocabulary: 600 most frequent shared types of length > 4.

τ is fixed at the 90th percentile of the pooled similarity distribution across the null corpora only. For the null set specified in §3 this is **$\tau = 0.2905$**.

The 90th percentile was selected by sweeping candidate percentiles **against the null alone**, before any value was computed for the test pair, and choosing the lowest regime that satisfies the §5 precondition while still measuring a tail rather than the bulk. The sweep is recorded in the registration JSON. No value from Plato, Aristotle, Pessoa, Kierkegaard or Josephus entered that selection.

Two quantities, **both required**:

- `L_corpus` — the two corpora pooled, blocked as single texts.
- `{L_ij}` — per-text-pair leaks; report median and IQR.

3. Null — empirical, and now built

61 matched cross-author pairs, 19 distinct author-pairings, drawn from: Xenophon, Philo, Plotinus, Josephus, Longinus, Herodotus (by book), Thucydides (by book), and the New Testament authors (Mark, Matthew, Luke–Acts, John, Paul, Hebrews). Capped at 6 pairs per author-pairing so that no single author dominates.

A within-author register set of 23 pairs across 5 authors is retained for the §7 sanity control.

The null is empirical rather than synthetic because five synthetic nulls were built and broken in the work preceding these registrations: the sum-to-zero constraint forced one to −1; the shared frequency baseline dominated another; a DTW alignment null was biased upward by the path's own selection of high-similarity cells (mean Z +0.76 across 100 routes); a coherence-destroying null inverted its sign, because homogenised blocks are *more* similar to each other; and a within-row permutation left the global multiset unchanged, making real and null identical by construction. Four of the five were reported as crossings before the artifact was found.

4. Matching — unchanged

- Token count within ±25% on both sides.
- Type–token ratio within ±15%.
- Prose only. Aristophanes excluded from the null, retained as a test case.
- Same edition family where available.

5. Preconditions — NEW, binding, checked before the test pair

The test may not proceed unless **all three** hold on the null alone:

1. **Non-degeneracy.** Zero null pairs with L = 0, and the 5th percentile strictly greater than zero. *(A deficit cannot be observed against a floor.)*
2. **Spread.** The null's 90th percentile is at least 5× its 5th percentile, so the distribution has room for a value to sit low without sitting at the edge.
3. **Size.** n ≥ 60 matched cross-author pairs.

If any precondition fails, the registration is spent and a third is required. The test pair is not computed.

6. Pre-registered outcomes and kill condition — unchanged

`L_corpus`	variance of `{L_ij}`	reading
below 5th pct of null	≥ null median	**the predicted signature**
below 5th pct	also below	corpus is merely narrow — NOT evidence
inside null	any	**the smoothing claim fails**
above null	any	ordinary intertextual relation

Kill condition. If `L_corpus` for Plato–Aristotle falls inside the central 90% of the natural distribution, the corpus-layer smoothing claim **fails and is reported as failed**. No post-hoc τ, no post-hoc matching, no re-slicing.

7. Controls — unchanged, both required

Positive. Pessoa's four voices, pooled two ways, must show the signature. If a documented configuration does not produce leak deficit, the statistic does not measure what it claims and

nothing about Greek follows. Kierkegaard second, with the standing caveat that his seat holds four pseudonymous works of roughly a dozen.

Sanity. Josephus — one author, four works, four registers, no design — must fall **inside** the natural distribution. If same-author-across-register reads as engineered, the statistic is detecting register and the test is void.

8. What a positive would, and would not, license — unchanged

Would. That the Platonic–Aristotelian corpus is anomalously smooth relative to natural Greek prose. A finding about the corpus, publishable whichever way the authorship question falls.

Would not. Design. Heavy editorial normalisation, transmission through a single recension, or a school trained to a house style would each produce smoothing without intent. Andronicus of Rhodes, constituting the Aristotelian corpus in the first century BCE from the cross-references the texts themselves contain, is sufficient on his own. A positive relocates the question; it does not answer it.

9. Why it is a test of the writer — unchanged

Plato writes inside a tradition he names: Sappho, Homer, the tragedians, the comic poets. He quotes them, stages them, argues with them, and in the *Republic* exiles them — the most famous act of literary criticism in the language, performed by a man in continuous and self-conscious competition with the people he is banishing.

This test asks about Plato as a **technician** — a maker of texts, measured on the properties of made things. Not the best doctrinarian. Not the best philosopher. The best **writer**, judged as one judges a craftsman: by what the artifact does that accident does not.

If the corpus is anomalously smooth, the claim is about craft — that these texts were finished to a standard natural prose does not reach, by someone who understood what a corpus leaks and did not permit it. And the *Republic*'s banishment reads differently: the poet who exiled the poets would be the most accomplished of them, the exile a move inside the art rather than against it.

It would let the poet back inside the polis.

DISPOSITION

DISCHARGED VOID — sanity control fired; no number from that run may be quoted

ENTRY — EA-YIELD-01

original sha256: `db3cb8aeec79d36afb8af8e59fe3cf515bb2ccfd19f501c793ab1940f2a0c815`
frozen text follows verbatim; do not edit

EA-YIELD-01 — Comparative Interpretive Yield

1. The question

Reading a corpus through a lens has different value in different corpora. "Transmission engineering" yields one thing for Plato and another for Herodotus. This registers a measure of that difference **before it is computed.**

2. The intuition being formalised

A lens has yield in a corpus when its markers behave as **one thing** there — when the features it groups actually co-vary across that corpus's works. If transmission engineering is a real dimension of Plato, then naming-gaps, form/matter talk, definition, homonymy and persistence vocabulary should rise and fall **together** across his works. If the lens is imposed, the markers will be independent, each tracking its own local subject.

3. Protocol statement (required before code, per Round 11)

Phenomenon. Does lens L pick out a coherent dimension of variation in corpus C, or a set of unrelated features?

Positive criterion. High mean pairwise correlation among L's marker-densities, computed across the works of C as units.

Nearest false positive. *Any* vocabulary set co-varies somewhat, because works differ in abstraction, register and length. A corpus with more heterogeneous works shows higher correlations for **any** marker set. Raw correlation is therefore uninterpretable.

Opportunity denominator. Every corpus receives the same lens, the same null construction, and the same unit (the work). Corpora with fewer than 8 works of ≥5,000 tokens are excluded for insufficient degrees of freedom, and the exclusion list is published with the result.

4. The statistic

For lens L with markers $m_1 \ldots m_k$ and corpus C with works $w_1 \ldots w_n$:

1. Compute density d_{ij} = occurrences of m_i per 10^4 tokens in w_j.
2. $\bar{r}$_obs = mean pairwise Pearson correlation over the $k(k-1)/2$ marker pairs.
3. **Null:** draw 500 random stem-sets of cardinality k, each stem **frequency-matched** to the corresponding real marker (within ±20% of corpus-wide rate), and compute $\bar{r}$ for each. This holds constant both cardinality and the base-rate structure.
4. **Yield** Y(L,C) = ($\bar{r}$_obs − μ_null) / σ_null.

Reported alongside: $\bar{r}$_obs, μ_null, σ_null, n works, and the per-marker densities.

5. THE LENS, FROZEN

Six marker families, fixed now and not to be adjusted after seeing results:

```
naming-gap        ανωνυμ | ωνομασ | ουκ εχει ονομα | ου κειται ονομα
form/matter       ειδ- (nominal) | υλ-
persistence       διαμεν- | σωζ- | φθειρ- | γενεσ- | διαδοχ- | παραδιδ-
definition        ορισμ- | οριζ- | τι ην ειναι
homonymy          ομωνυμ- | συνωνυμ- | πολλαχ-
memory/writing    μνημ- | γραφ- | ληθ-
```

6. CORPORA

plato · aristotle · xenophon · herodotus · thucydides · philo · plotinus · josephus · aristophanes. Within-cluster comparison is permitted here because the measure is **per corpus**, not between-corpus pairing; M33's firewall governs pairwise controls, which this is not. Plato and Aristotle are nonetheless reported separately and never pooled.

7. REGISTERED PREDICTION

Lee Sharks, before execution: *strong convergent yield across Plato–Aristotle.* Both corpora should show Y substantially above the comparison corpora, and comparable to each other.

Recorded outcomes and their readings:

pattern	reading
Plato and Aristotle both high, others low	**prediction confirmed**
One high, one low	the lens is one author's concern, not a shared technology
All corpora comparable	the lens describes philosophical prose, not this corpus
Herodotus/Thucydides high	the markers track narrative, and the lens is misspecified

8. KILL CONDITIONS, BINDING

- If Y(transmission, Plato) and Y(transmission, Aristotle) are **not both above the median** of the nine corpora, the prediction fails and is reported failed.
- If the null cannot be frequency-matched (insufficient stems at a marker's rate), the measure is **VOID** for that corpus and reported void, per the EA-LEAK-DEFICIT-02 precedent.
- **No post-hoc adjustment of the marker set.** It is frozen in §5.

9. STATED LIMITATIONS, BEFORE THE FIRST NUMBER

It measures coherence, not truth. A well-constructed wrong lens scores high. Y is evidence that a lens describes a real dimension of variation, never that the dimension is what the lens says it is.

A lens can fail by being too successful. A concern saturating every work of a corpus shows no variance, therefore no correlation, therefore Y ≈ 0. **Low yield is ambiguous between**

absence and saturation, and the measure cannot distinguish them. This is its principal defect and it is registered here rather than discovered later.

Genre is not controlled. M28 established that subject determines shape in Aristotle at Z = +4.25. A lens may cohere because the corpus's works vary by domain and the markers track domain. The companion measure — **residue absorption**, regressing each marker on domain first and testing whether the residuals still co-vary — is specified as the required follow-up and is **not** run here.

Consequently a positive result licenses the residue-absorption test and nothing further.

DISPOSITION

SPENT — marker co-variance was the wrong observable; saturation defect predicted in its own §9 and realised

---

ENTRY — EA-YIELD-02

original sha256: `7bcbbb0fbe69c82ce307c3f7c54c9c828c66914dfc80510b64bdc669453e4e88`
frozen text follows verbatim; do not edit

EA-YIELD-02 — Reorganization Yield

1. Why EA-YIELD-01 was the wrong measure

EA-YIELD-01 measured whether a lens's **vocabulary co-varies** across a corpus's works. It returned Plato +0.85, Aristotle +1.20, Philo +1.08, with six of nine corpora void or excluded because narrative and comic Greek carry no frequency-matched stems for *definition* or *naming-gap*. Correlations were near zero everywhere.

That was the wrong observable. Interpretive yield is not lexical. It is the degree to which a lens **reorganizes and develops** a corpus according to the lens's own shape — Parry's criterion: the tradition reorganizes around the reconstruction with more coherence than under the alternatives.

EA-YIELD-01 is marked **spent, prediction unconfirmed, defect (saturation blindness) predicted in §9 and realised.**

2. The measure

A lens has a **shape**: a set of functional slots. Yield is measured by whether the corpus fills those slots — **distinctly, without forcing** — and whether the resulting arrangement **develops**, i.e. predicts placements not used to build it.

Three quantities, scored per corpus and per unit level:

Coverage — how many slots are filled by at least one unit. **Sharpness** — for each unit, does it fit one slot decisively or smear across several? Scored as the concentration of a unit's slot-assignment weights. **Development** — number of placements the arrangement predicts that were not used in constructing it, and how many hold on inspection.

3. THE LENS, FROZEN — transmission engineering

Six slots, from the archive's own specification of the Sapphic apparatus (#503, #1483, #1054), fixed now:

```
T1 ENCODING          committing a voice to a substrate; the problem of writing
T2 SUBSTRATE         the material that receives and holds the impression
T3 DECOMMISSIONING   the live speaker's channels shut down; the body ends
T4 WITHHOLDING       what is deliberately not supplied, so a receiver must complete
T5 RECOVERY          activation in a later mind; what was held becomes live again
T6 VERIFICATION      distinguishing genuine transmission from counterfeit
```

4. RIVAL LENSES, FROZEN — the null

Scored identically, by the same assigner, on the same units. Each has six slots.

R1 — The Four Causes + 2 (Aristotelian organizing scheme): material · formal · efficient · final · potentiality · actuality

R2 — The Divided Line (Platonic organizing scheme): εἰκασία · πίστις · διάνοια · νόησις · the Good · the ascent

R3 — The Cardinal Virtues + 2: wisdom · courage · temperance · justice · piety · the unity of virtue

R4 — Random control: six slots drawn from an unrelated domain — agriculture · navigation · medicine · warfare · commerce · weather

If the transmission lens does not beat R1–R4 on coverage and sharpness, **it has no yield** and the result is reported as such.

5. UNIT LEVELS — per Lee Sharks's specification

The same corpus is scored at multiple granularities, because a lens may organize at one level and not another. This is the measure's chief novelty.

```
L1 BOOK/WORK      individual work (a dialogue, a treatise, an NT book)
L2 AUTHOR-GROUP   works grouped by declared author
                  (Johannine: Gospel + 1-3 John + Revelation;
                   Pauline undisputed; Lukan: Luke + Acts; Platonic; Aristotelian)
L3 WHOLE CORPUS   the New Testament entire; the Platonic corpus entire;
                  the Aristotelian corpus entire
L4 CROSS-CORPUS   Plato + Aristotle treated as one object
```

The registered expectation is that yield varies by level, and that the level at which a lens organizes is itself the finding. A corpus may fill all six slots at L3 while no single

work fills any at L1.

6. CORPORA

`plato · aristotle · gnt-nestle1904 · philo · xenophon · herodotus`

The New Testament is included at all four levels and is the measure's most informative case, having a documented multi-author structure with contested attributions — the condition the Platonic corpus is being tested for.

7. ASSIGNMENT PROTOCOL — the anti-circularity rule

Assignments are made from received characterization, not from my reading. For each unit, the slot assignment must be justifiable by what the scholarly tradition says the work is *about*, stated before the slot is named. Where the received characterization does not support any slot, the unit scores **unfilled** — and unfilled units are reported, not dropped.

No unit may be assigned to a slot on the strength of a passage discovered during this investigation. The *Letter* XIII σύμβολον, the *Phaedo* 59b self-absence, and the M34 exclusion are **development predictions** (§2), not assignment evidence, and are scored in the development column only.

8. REGISTERED PREDICTIONS

Lee Sharks: strong convergent yield across Plato–Aristotle.

Derived, and recorded so they can fail: - Plato at L1 fills all six slots with six *different* dialogues, no overlap. - The NT fills poorly at L1, better at L2, best at L3 — the signature of a corpus organized above the level of its books. - If Plato behaves like the NT (poor at L1, strong at L3), that is evidence the Platonic corpus is organized above the level of its dialogues. - If Plato fills at L1 where the NT fills only at L3, the two are **structurally different objects** and the extended-corpus thesis loses its closest analogue.

9. KILL CONDITIONS, BINDING

- If any rival lens R1–R4 achieves coverage and sharpness within 1 slot of the transmission lens on Plato, the measure shows **no differential yield** and is reported as showing none.
- If R4 (the random control) scores above 3 of 6 coverage on any corpus, the **assignment protocol is too permissive** and the entire run is VOID.
- No slot may be redefined after seeing an assignment. The lens is frozen in §3.

10. STATED LIMITATIONS

The assigner is not blind. I know the hypothesis. §7's received-characterization rule is the mitigation and it is imperfect; a genuinely blind protocol would need an assigner who does not know which lens is under test, and that is not available here. **This is the measure's principal weakness and it is registered before execution.**

Coverage is coarse. Six slots and a handful of corpora give a low-resolution statistic. The measure can detect a large difference and nothing subtle.

Development is the strongest column and the least formal. A prediction that "holds on inspection" is judged, not computed. Every development claim must cite the passage and be independently checkable.

DISPOSITION

DISCHARGED — prediction confirmed; both corpora fill 6/6 at L1 with matched slots

---

ENTRY — EA-COMPLETE-01

original sha256: `c185adb40e7b33df31218460b313a5e5db8d330bdcab75b04b0fa36ee40a1c80`
frozen text follows verbatim; do not edit

EA-COMPLETE-01 — Completion of Abandoned Executions

1. The question this exists to answer

Every positive result in this investigation is consistent with school transmission. M30's reflex, EA-YIELD-02's slot convergence, M34's exclusion — a school inheriting a transmission programme produces all of them. **What would isolate single-author convergence that would not be present in school transmission?**

2. Why reported correction is the wrong observable

The first attempt measured whether Aristotle **corrects Plato's method** at the rate he corrects others'. It returned: inside the Organon — the works *about* method — Plato appears four times, all in the *Topica*, and **all four as examples of definitional error** (genus-in-species; non-established names; soul as self-moving number; "mortal" attached in animal definitions).

That is evidence FOR the school hypothesis and it is admitted as such. A student cataloguing the master's errors in a methodology textbook is exactly what teaching looks like.

But it measures the **wrong thing**. A reported correction is a *statement*, and statements are precisely what a school transmits — including the statement that the master erred. It cannot discriminate.

3. The right observable: what happens at the operation

λόγος-level correction is not Aristotle *saying* Plato erred. It is Aristotle **executing the same operation and taking a different branch** at the point where it could go either way.

Three possible relations at each matched slot:

```
(a) SAME        Aristotle executes as Plato does
(b) CORRECTED   Aristotle executes a repaired version of a stated error
(c) COMPLETED   Aristotle finishes an execution Plato ran and ABANDONED
```

(c) is the diagnostic case. An abandoned operation is not a statement; it is a hole with a shape. Completing it requires reading the failure as **unfinished rather than refuted** — and Plato presents these failures as refuted (*ὃ ἔφαμεν ἀδύνατον*). A student inherits the refutation. Completion inherits the shape of what failed and supplies the missing part.

This is Maas's *errores coniunctivi* one level up: shared **correct** method proves nothing because both hypotheses predict it; what separates them is a shared arbitrary structure that could not be transmitted as doctrine, **because the doctrine says it failed.**

4. THE OBSERVED CASE — T2, which motivated the registration

Plato, *Theaetetus* 196c — the wax block, at its abandonment: > οὐκοῦν εἰς τοὺς πρώτους πάλιν ἀνήκει λόγους ... **ὃ ἔφαμεν ἀδύνατον**

Aristotle, *De anima* 424a — the same analogy, as doctrine: > καθόλου δὲ ... **δεῖ λαβεῖν** ὅτι ἡ αἴσθησίς ἐστι τὸ δεκτικὸν τῶν αἰσθητῶν εἰδῶν > **ἄνευ τῆς ὕλης**, οἷον ὁ κηρὸς τοῦ δακτυλίου ἄνευ τοῦ σιδήρου

The completing mechanism is **ἄνευ τῆς ὕλης — form without matter**, which is the snub doctrine. Plato's block had no way to separate impression from material, which is why it collapsed into the eleven-for-twelve problem.

5. REGISTERED PREDICTION

At the remaining five slots (T1, T3, T4, T5, T6):

1. Plato's execution terminates in **aporia or abandonment** — ἀδύνατον, ἀπορ-, οὐκ ἔχω, an explicit dropping of the model.
2. Aristotle's terminates in **doctrine** — δεῖ λαβεῖν, φανερόν, εἴρηται, a stated result.
3. **The strong conjunct:** the completing mechanism is **the same across slots** — the form/matter distinction, or its immediate apparatus.

Prediction 3 is what would make this more than influence. Influence predicts completion by *various* means. A single configuration predicts completion by *one* means.

6. KILL CONDITIONS, BINDING

- If fewer than **3 of 6** slots show the Plato-abandons/Aristotle-completes pattern, the test fails and is reported failed.
- If the completing mechanisms are **heterogeneous** across the slots that do show it, prediction 3 fails and only ordinary influence is supported — which is the received view and no advance.
- If Plato's slot-executions terminate in **doctrine** rather than aporia, the premise is wrong and the whole test is void.
- No slot may be reassigned. The six are fixed by EA-YIELD-02 as discharged.

7. STATED LIMITATIONS

n = 6. Six slots is a small denominator and no result here can be strong on its own.

Aporia is a Platonic genre convention. Dialogues end open as a matter of form. The test must therefore compare *the specific operation's* termination, not the dialogue's, and must accept that the base rate of Platonic aporia is high. **This is the principal confound and it is registered before execution.**

"Completion" is judged, not computed. Whether *De anima* 424a completes *Theaetetus* 196c rather than merely resembling it is an interpretive claim. Every completion claim must cite both passages and the specific missing part supplied.

The assigner is not blind — the same weakness as EA-YIELD-02 §10, unmitigated.

DISPOSITION

DISCHARGED — predictions 1,2 hold 5/6; prediction 3 first scored FAILED then CORRECTED to holds on 3 of 4

ENTRY — EA-UNRES-01

original sha256: `a68bf7f2ee54b1af2777bc5964ab92a1936bc38c489e549a0bf254450ae71b87`
frozen text follows verbatim; do not edit

EA-UNRES-01 — Engineered Unresolvability and Its Key

1. The reframing, and why it has been restated four times without being built

The investigation has repeatedly treated non-resolution as **instrument failure**: substrate stylometry returning ordinary (M4–M28), the Poisson voiding on its own sanity control (M25), YIELD-01's correlations at zero, the base rate declining the *Republic*/*Symposium* question (Round 7). Each was filed as a defeat.

Under the transmission reading they are the artifact behaving as specified. EA-FLOOD-01 already states that unresolved disputes are the copying mechanism — a settled attribution is finished, an unsettled one must be re-adjudicated in every generation, and adjudication is transcription. EA-PINAX-01, corrected, already predicts that criteria **fail to converge** here. Both were recorded, and the investigation then went on trying to make them converge.

And the reading is falsifiable. Ordinary corpora are ambiguous *unevenly*. Engineered unresolvability would be ambiguous *cleanly*.

2. PART A — the signature of engineering

Claim. Natural ambiguity and engineered ambiguity have different shapes.

```
NATURAL       uneven — some works resolve, some don't; evidence accumulates
              directionally; new instruments move the needle; attention closes
              questions over time
ENGINEERED    flat — resolution stalls at the same place regardless of
              instrument; disputes do not drift toward settlement; attention
              does not close them
```

Three observables:

A1 — instrument-invariance. Do unrelated instruments return the same non-answer? Fifteen distinct measures were run on Plato–Aristotle in one session and every substrate measure returned ordinary. That is a datum, not a defeat, and it requires a comparison class.

A2 — flatness of resolution. In a natural corpus, per-work attribution confidence should be **highly uneven**. Engineered would show suspiciously flat non-resolution across the corpus.

A3 — persistence under attention. Ordinary disputes settle as scrutiny increases. The Platonic dubia, the Aristotelian corpus boundary and the Pauline question have stayed open for centuries **while attention rose**.

The control, and why it is the right one. EA-CORPORA-08 seats the nine Attic orators: same period, same language, same transmission conditions, same manuscript ecology, **no configurational hypothesis attached to any of them** — and their attribution questions largely *did* resolve. Antiphon's *Tetralogies* are disputed and the dispute has a definite shape; Demosthenes carries works confidently athetized. If Plato–Aristotle shows **flatter, more persistent and more instrument-invariant** non-resolution than Isaeus–Demosthenes, that is the measurement.

 PART A IS BLOCKED, and the blocker is stated before any result. Of the corpora required, **only Aristotle carries per-work attribution status** (48 of 48). Plato has none. The nine orator seats have none. Part A therefore requires a metadata assembly — per-work received status, date of first athetesis, and current scholarly disposition — for Plato and the orators, from sources not currently in the archive. **No Part A number may be reported until that exists.**

3. PART B — the key

The constraint, from Lee Sharks: engineered unresolvability **must contain its key** — a placed signature confirming artifice. This is Round 5's correction applied forward: a construction good enough to be undetectable must leave something that confirms it, or the construction defeats its own purpose.

Criteria for a key, frozen now:

```
K1 PROMINENT    structurally placed so it can be found — terminal, initial,
                or at a titular position
K2 INERT        does no work under the ordinary reading; a reader without the
                hypothesis passes it without stopping
```

```
K3 DECISIVE     under the configurational reading it is not merely consistent
                but confirming
K4 ARTIFICE     it must indicate MAKING, not merely absence or uncertainty
```

CANDIDATE SET, frozen before evaluation:

```
C1  Letter II 314c    οὐδ᾽ ἔστιν σύγγραμμα Πλάτωνος οὐδὲν οὐδ᾽ ἔσται, τὰ δὲ
                      νῦν λεγόμενα Σωκράτους ἐστὶν καλοῦ καὶ νέου γεγονότος
C2  Letter XIII 360a  ἀντιλέγεται ὡς οὐ Πλάτωνος — the athetesis transmitted
                      INSIDE the text — followed by ἀρχή σοι τῆς ἐπιστολῆς
                      ἔστω καὶ ἅμα ΣΥΜΒΟΛΟΝ ὅτι παρ᾽ ἐμοῦ ἐστιν
C3  Symposium 223d    τοῦ αὐτοῦ ἀνδρός — the demand, with its proof destroyed
                      in transmission and the witnesses asleep
C4  Phaedo 59b        Πλάτων δὲ οἶμαι ἠσθένει — the author writing himself
                      absent from the founder's death
C5  Statesman 260e    αὐτεπιτακτική coined for the self-commanding, kings
                      placed INTO it, other genera left unentered
C6  Theaetetus 209c   the μνημεῖον that must be deposited to individuate, and
                      is not
```

Scoring: each candidate against K1–K4, and — the part that makes it a test rather than a reading — **against the same base rate in the orator control.** How many statements meeting K1–K4 does a non-configurational corpus of comparable size contain? If the orators yield comparable candidates, the Platonic set is unremarkable and Part B fails.

4. KILL CONDITIONS, BINDING

- **Part A** fails if Plato–Aristotle non-resolution is not flatter, more persistent, or more instrument-invariant than the orator control on at least two of A1–A3.
- **Part B** fails if the orator control yields candidates meeting all four of K1–K4 at a comparable rate.
- **The candidate set is frozen.** No passage may be added to C1–C6 after scoring begins.
- Part A results may not be reported before the metadata assembly exists.

5. STATED LIMITATIONS

Attention is confounded with everything. Plato and Aristotle have been read more than the orators by orders of magnitude. More attention produces more disputes and more persistence of disputes. Normalising for this is the hardest part of Part A and may not be possible; if it is not, Part A is **void**, not adjusted.

Survivorship. The orators' resolved disputes may be resolved because the losing texts were discarded, while the Platonic corpus retained its disputed members. That is itself a difference in transmission behaviour and may be the finding rather than a confound — but it cannot be both, and which it is must be decided before Part A runs, not after.

Part B's assigner is not blind, and the candidate set was assembled by the same reader who formed the hypothesis. The orator base-rate is the only real control and it is doing all the work.

DISPOSITION

PART B DOES NOT FAIL (2 of 6 candidates, orator control zero); PART A BLOCKED on attribution metadata

---

ENTRY — EA-UNLOCK-01

registered: 2026-08-29, before any target below was examined **frozen text follows verbatim; do not edit**

EA-UNLOCK-01 — The Unlocking Prediction

1. What is being predicted

Not "we will keep finding interesting similarities" — uselessly permissive. The claim is specific:

> **Structures that were independently puzzling, or independently measured, before the hypothesis was applied will repeatedly become MORE DETERMINATE when Plato and Aristotle are read as positions inside one construction — without altering the local philology to make them fit.**

2. The two admissible forms

```
FORM A   Platonic execution or problem  →  Aristotelian explicit account
         or apparatus, where the Aristotelian side names or completes what
         the Platonic side performs without naming.

FORM B   A statement in one corpus + a statement in the other → an operation
         visible ONLY across the partition, recoverable by neither alone.
```

M40 is the cleanest instance of B on record: Plato supplies syllogizing; Aristotle identifies it as syllogizing (*APr* I.31); Aristotle claims the development of syllogizing and negates prior partial development (*SE* 183b) — and the relation must itself be recovered syllogistically.

3. HYPOTHESIS HELD AT MAXIMUM — it must be able to lose

```
H_H : one maker, deliberately partitioned as Plato and Aristotle.
```

No weakening to protect it. If it is weakened to survive a failure, the weakening is itself recorded as a failure.

4. TARGETS FROZEN NOW — chosen before examination

Each is an item the register already lists as open, unexplained, or dangling. **None has been examined for this purpose.**

```
T-A  The 31-term class (Round 2 §13). Identified, never characterised.
     Do they share a semantic character, or is the list arbitrary?
T-B  Directionality (§15). Does ANY term run terminal-Aristotelian →
     technical-Platonic? Under received chronology it cannot.
T-C  M27's unexplained near-equality: self-speaking 25.3 (Plato dramatic)
     vs 29.0 (Aristotle), across the two most formally opposed prose bodies.
     Recorded as "a measurement without an account."
T-D  The Republic/Symposium comedy-tragedy pair, CONTENT base rate — never
     attempted; only the form base rate was run (Round 7).
T-E  Theaetetus 209c's argument structure, extracted and searched in
     Aristotle INDEPENDENTLY of the word σιμ- (never done; Round 3 searched
     doctrine-vocabulary, Round 4 argument-shapes).
T-F  The four Platonic naming-gap works (Sophist, Statesman, Theaetetus,
     Timaeus) — is there an Aristotelian counterpart naming what they
     perform?
```

5. SCORING — fixed before running

Each target resolves to exactly one of:

```
UNLOCK    becomes more determinate under H_H, in Form A or B, WITHOUT
          adjusting the local philology
NULL      no change in determinacy either way
FAILURE   becomes LESS determinate under H_H, or the reading requires
          altering the philology to fit
```

Reverse-engineering test, binding. An UNLOCK counts only if the target was on this frozen list AND the resolving passage was not selected by searching until something fit. Any case where the passage was found by open search is scored **NULL regardless of how good it looks.**

6. KILL CONDITIONS

- Fewer than **3 UNLOCKS in 6** → the unlocking claim fails.
- **2 or more FAILURES** → H_H at maximum is damaged and must be reported so.
- Any weakening of H_H mid-run to accommodate a result → the run is **VOID**.
- Targets may not be added, swapped, or reworded after this registration.

7. WHAT A POSITIVE WOULD AND WOULD NOT BUY

Would. The object requiring explanation stops being any individual correspondence and becomes **the recurrence of the unlocking operation itself**:

```
P(E_n+1 | H_H, E_1…E_n)  >>  P(E_n+1 | H_S, E_1…E_n)
```

At which point “inheritance can also explain each one” ceases to be adequate, because it is no longer the individual cases that need explaining.

Would not. Establish one historical hand. The three propositions stay distinct and are recorded here at their current standing:

```
Plato–Aristotle form one functional/intellectual corpus   STRONGLY SUPPORTED
one latent construction explains it economically          INCREASINGLY PLAUSIBLE
one historical hand wrote both received corpora           LIVE, NOT ESTABLISHED
```

8. STATED LIMITATION

The assigner is not blind and knows the hypothesis. The freeze on targets and the reverse-engineering rule in §5 are the only mitigations, and they are imperfect: **the scoring of "without adjusting the local philology" is a judgement.** Every UNLOCK must cite its passages so the judgement is checkable.

DISPOSITION

RUNNING. T-F run 2026-08-29 and scored **NULL** — three of four resolve in Form A with exact Greek (Theaetetus→De Anima 412a, Sophist→De interpretatione 16a, Statesman→Politics 1275a), but inheritance predicts Form A equally strongly, so the differential-determinacy requirement of §5 is not met. Notebook Round 17 §62.

Running total: 0 unlocks, 1 null, 5 targets remaining (T-A, T-B, T-C, T-D, T-E), threshold 3.

ENTRY — EA-RELFORM-01

registered: 2026-08-29, before any control corpus is scored **frozen text follows verbatim; do not edit**

EA-RELFORM-01 — The Relational Form Measure

1. What this exists to prevent

Every control this investigation has tried has failed for one of two reasons: the candidate could not be secured **outside** the hypothesis space (Theophrastus, M36; Xenophon and Aristophanes, M33), or the operation being counted **did not occur** there (the Attic orators, Round 14 §56).

And the framing itself was wrong: I proposed testing whether control pairs "reproduce the Plato–Aristotle signature," which is content-bound to this corpus and would have measured whether the controls are themselves inside the configuration (M43c).

This registration fixes the measure with no Greek content in it.

2. THE THREE RELATIONAL FORMS — frozen

```
R1  COMPLEMENTARY COVERAGE
    Is each side internally tight while their union is materially more
    complete than either alone?
```

```
    Inheritance predicts REDUNDANCY — the student possesses what the master
    taught, so the union barely exceeds the parts.
    Scored as: coverage(A∪B) / max(coverage(A), coverage(B)), against
    redundancy |A∩B|/|A∪B|, over a functional inventory defined per
    tradition, NOT over vocabulary (M37 showed vocabulary fails: every pair
    lands in 0.20–0.34 and documented succession is indistinguishable from
    documented independence).

R2  ABANDONED-EXECUTION COMPLETION
    Does the successor complete operations the predecessor explicitly
    ABANDONED — declared aporetic, impossible, or refuted — rather than
    extending ones the predecessor finished?
    Scored as: completions / abandonments-available-to-the-successor.
    THE DENOMINATOR IS REQUIRED. A numerator without it is what Round 13
    produced and could not interpret.
    Severity weights, frozen: same problem · same constraint retained ·
    same distinctive figure retained · missing mechanism supplied ·
    prior text calls the route impossible.

R3  ARBITRARY PROCEDURAL AGREEMENT
    Shared habits the method does not require — defined generically, never
    as a particular habit.
    ⚠ SCORED ON INDEPENDENT WORKS ONLY. See §4.
```

3. LABELLED CLASSES — labels from documentary evidence, never from text

H	one person, multiple authorial positions	Pessoa; Kierkegaard
S	master–student succession	Albert→Thomas; Ibn ʿArabī→ Qūnawī; Tsongkhapa→Khedrup; Maimonides→Abraham Maimonides
C	distinct-author collaboration	Luther/Melanchthon
I	independent, same tradition	
O	single-author corpus under one name	Josephus

Admissibility, binding: a figure enters the S class only if attested by evidence with **no relation to textual style, doctrinal similarity, or any succession tradition under test** — canonization proceedings, university registers, papal bulls, chapter records, monastic administration. **Thomas Aquinas passes. Theophrastus does not.**

The null is HARD by construction: not random distinct authors — Plotinus and Philo barely knew each other, so their nulls are uninformative — but **securely distinct authors under MAXIMAL transmission pressure**, a disciple who lived in the master's household.

4. THE CONTAMINATION RULE

Albert and Thomas both write Aristotle commentaries. Any Aristotelian reflex appears in both **by construction**. Verified: Borgnet vol. 7 carries *innominat-* ×13, but as a gloss on *NE*

1107b–1108a, the passage that performs the reflex.

```
COMMENTARY WORKS    R1, R2 admissible (properties of the RELATION)
                    R3 INADMISSIBLE (shared-source contamination)
INDEPENDENT WORKS   all three admissible. This is the clean test.
```

Every pair is scored commentary and independent-work separately, and the contamination is declared on the commentary half.

5. ORDER OF OPERATIONS — binding

1. Seat the control corpora.
2. Define and calibrate R1–R3 on the labelled classes, WITH PLATO–ARISTOTLE NOT IN VIEW.
3. Demonstrate out-of-sample separation of H from S.
4. ONLY THEN score Plato–Aristotle, as ONE INSTANCE of the general measure.

If step 3 fails — if the measure cannot separate Pessoa's relationships from documented teacher-successor relationships — the instrument has failed and says nothing about Plato. That is a real kill condition and it fires before the target is ever scored.

6. FEASIBILITY, CHECKED 2026-08-29

```
Thomas Aquinas   corpusthomisticum.org, HTTP 200, structured HTML,
                 ISO-8859-1, no OCR                          FEASIBLE
Albert           archive.org DjVuTXT, 220 items; vol. 7 = 338,391 tokens.
                 OCR: frequent vocabulary clean, scattered errors in rare
                 forms → USABLE for function-word and structural measures,
                 UNSAFE for rare-lexeme measures. Declare on the seat.
Doc. Cath. Omnia HTTP 403                                    BLOCKED
Ibn ʿArabī, Tsongkhapa, Maimonides                           UNCHECKED
```

7. STATED LIMITATIONS

R1's functional inventory must be defined per tradition, which is a judgement and the weakest joint in the design. It must be fixed and published before scoring, and the same inventory logic applied to every pair.

R2's denominator requires identifying abandonments in each corpus, which is interpretive. Every abandonment counted must cite its passage.

The assigner is not blind. §5's order of operations is the only mitigation and it is imperfect.

DISPOSITION

PENDING — registered before any control corpus is seated or scored.

ENTRY — EA-SPEC-01

registered: 2026-08-29, before any Platonic speaker is measured **frozen text follows verbatim; do not edit**

EA-SPEC-01 — The Specification-Depth Hypothesis

1. What Pessoa showed (Round 22, characterization on documented ground truth)

Ratio of a position's internal dispersion to its distance from the other positions, in a corpus whose single authorship is documented:

```
Caeiro     1.781    no philosophy, no memory, no interiority — sensation only
Soares     1.632    one street, one office, one clerk, one register
Mora       1.437    one doctrine, argued
Reis       1.374    one meter, one stance
Campos     1.129    everything, at maximum volume
ORTHONYM   1.033    no restriction at all
```

2. THE HYPOTHESIS

Container tightness tracks the SEVERITY OF THE CONSTRAINT placed on the position, not similarity and not disguise.

A heteronymic series is a search downward: *what is the least one can specify and still get a self that coheres?* Each position subtracts something and tests whether a voice survives the subtraction. Caeiro is the floor of the Pessoan series — remove more and no one is there. The orthonym, specified by nothing, does not contain at all.

So the ratio measures SPECIFICATION DEPTH. A container is tight because something was taken away, and the number is how much.

3. THE PLATONIC TEST — prediction registered before measurement

If specification depth drives tightness, then **the unit is the SPEAKING POSITION, not the work.** Plato's corpus is voiced: Socrates, the Eleatic Stranger, Timaeus, the Athenian, Parmenides, Diotima (reported), Aristophanes (constructed), Protagoras, Callicles.

PREDICTION, frozen:

```
P1  Speaker tightness will ORDER BY CONSTRAINT SEVERITY: the more narrowly a
    speaker is specified — one doctrine, one register, one occasion — the
    tighter the container.
P2  The LEAST constrained speaking position will sit NEAREST 1.0.
P3  Direction is what is predicted, not magnitude. Greek function-word space
    is not Portuguese function-word space and the ratios are not
    cross-comparable.
```

Ranking by constraint, fixed NOW, before any measurement:

MOST CONSTRAINED	Timaeus	one continuous cosmological monologue
	Diotima	reported speech inside a report, one doctrine
	Aristophanes	one myth, comic register (M16)
	Eleatic Stranger	method-bound, division throughout
	Parmenides	one exercise, exhaustively run
	Athenian	one subject, legislation
	Protagoras/ Callicles	set-piece opponents, one position each
LEAST CONSTRAINED	SOCRATES	every subject, every register, every dialogue

4. KILL CONDITIONS, BINDING

- If the ordering is **uncorrelated** with the pre-registered constraint ranking, the hypothesis fails.
- If **Socrates is not among the loosest**, P2 fails and the hypothesis fails with it — Socrates is the least constrained speaker in the corpus and the prediction is unambiguous.
- The constraint ranking above may **not be revised after measurement**.
- Speakers with under 6,000 tokens are excluded before scoring, and the exclusion list is fixed by token count alone.

5. WHAT A POSITIVE WOULD AND WOULD NOT BUY

Would: evidence that the Platonic corpus is organized by specification depth in the way a documented heteronymic system is. That is a structural parallel with a known case, measured on a pre-registered ordering.

Would NOT: any conclusion about who wrote what. A dramatist constructing characters would also specify them to differing depths, and would also produce tighter containers for narrower roles. **This measures construction, which dramatic composition and heteronymic composition share.** It cannot separate them and is not registered as if it could.

6. STATED LIMITATIONS

Speaker attribution in the dialogues must be extracted mechanically and every speaker's token count published. Where Plato reports speech within speech — Diotima inside Socrates inside Apollodorus — the nesting is declared, not resolved.

Function-word profiles may be the wrong instrument for verse and for dialogue-turn structure. The Pessoa result carries this caveat unresolved (Round 22 §87) and it carries forward here.

The assigner is not blind. §3's ranking is frozen in this text as the only mitigation.

DISPOSITION

RUN 2026-08-29. P2 HOLDS — Socrates rank 1 of 7 from the loose end at 1.166, and Timaeus tightest at 1.649, both as frozen. **P1 PARTIAL** — the direction holds but the Eleatic Stranger lands second-loosest where he was ranked constrained. **Most of the frozen ranking was untestable**: Diotima, Aristophanes, Parmenides, Protagoras and Callicles all fall under the 6,000-token threshold. Extraction flaw recorded: TI and TIM-mono overlap.

And the UNIT is wrong — M16 shows speaker-differentiation is sometimes deliberately switched off, so a per-speaker measure reads absence of construction as absence of a position. Work-level is the next run. Notebook Round 23.

ENTRY — EA-CAPTURE-01

registered: 2026-08-29, before any term set is drawn under the fixed rule **frozen text follows verbatim; do not edit**

EA-CAPTURE-01 — Reception Capture, With the Term-Selection Rule Fixed in Advance

1. Why this registration exists

M46 measured reception capture across four pairs and found them ordering: Caeiro/interpreters (H, documented) TOTAL; Plato/Aristotle (under test) PARTIAL at 25–35×; Either-Or A/B (H, documented) PARTIAL at 4.7–14×; Aristotle/Aquinas (S, documented) NONE.

That result is not admissible as it stands. I chose the term sets myself, separately for each corpus, after looking at each. That is the reverse-engineering hazard EA-UNLOCK-01 §5 exists to score against. **The ordering is suggestive; the magnitudes are not comparable.**

2. THE SELECTION RULE — frozen, mechanical, identical for every pair

For an ordered pair (INTERPRETED, INTERPRETER):

```
1.  Take the interpreter's text ONLY. Compute content-word frequencies,
    excluding function words and proper names.
2.  Take the interpreted position's text ONLY. Compute the same.
3.  The TERM SET is the N = 30 content words with the highest
        rate_in_interpreter / (rate_in_reference_corpus)
    where the reference corpus is the whole seated corpus of that language,
    so the set is "what is distinctive of the interpreter's discourse" —
    **computed WITHOUT reference to the interpreted position.**
4.  ONLY THEN count those 30 terms in the interpreted position.

CAPTURE SCORE = median over the 30 terms of
```

```
                    rate_interpreter / rate_interpreted
with rate_interpreted floored at 1 occurrence to keep the ratio finite,
and the count of terms at ZERO in the interpreted position reported
alongside as the ZERO-COUNT.
```

Step 3 is the whole point: the term set cannot see the interpreted position.

3. PAIRS — fixed now, with their class labels

```
H  documented one maker, multiple positions
   H1  Alberto Caeiro          ← Mora + Campos + Reis writing on Caeiro
   H2  Either/Or A             ← Either/Or B
S  documented distinct persons in succession
   S1  Aristotle               ← Aquinas
   S2  HEGEL                   ← MARX          □ the control Lee specifies
?  under test
   T1  Plato                   ← Aristotle
```

S2 is the decisive control. Marx supplies the vocabulary through which Hegel is now read — *inversion*, *mystification*, *standing on his head*, *the rational kernel*, *ideology* — and Marx and Hegel are securely distinct persons with no possible configurational relation. **If S2 scores like the H pairs, reception capture is not diagnostic of authorship at all, and M46 collapses.**

4. PREDICTIONS, REGISTERED

```
P1  H1 and H2 score HIGH capture with HIGH zero-counts.
P2  S1 (Aquinas) scores LOW — established already, and serves as the
    instrument's negative check.
P3  S2 (Marx on Hegel) is THE OPEN QUESTION. No direction is predicted.
P4  T1 (Plato/Aristotle) is scored last and its value is reported against
    whatever range S2 establishes.
```

No prediction is made about T1 beyond that it will be reported.

5. KILL CONDITIONS, BINDING

- **If S2 scores within the H range, the measure is not diagnostic and M46 is withdrawn as evidence.** This is the condition most likely to fire and it is registered as such.
- If S1 and S2 diverge widely from each other, the S class is not a class on this measure and the comparison fails.
- The selection rule may not be altered after any pair is scored.
- Translation is permitted (the measure counts concept distribution, not style), but each pair must be scored in ONE language throughout, and the language is declared.

6. FEASIBILITY

```
H1  pessoa-full            SEATED
```

```
H2  kierkegaard            SEATED (Either/Or I and II, Danish)
S1  aristotle + aquinas    SEATED (cross-linguistic — declared limitation)
S2  Hegel + Marx           marx SEATED; HEGEL NOT SEATED — required
T1  plato + aristotle      SEATED
```

S2 cannot run until Hegel is seated. That acquisition is the blocker.

7. STATED LIMITATIONS

The reference corpus for step 3 differs per language, so "distinctive of the interpreter" is computed against different baselines. This is a real non-comparability and cannot be removed without a single multilingual reference.

Content-word extraction is language-specific and the stop-lists are mine.

S1 is cross-linguistic — Latin interpreter, Greek interpreted — where every other pair is monolingual. Its score is therefore the least comparable of the five and is retained mainly as the instrument's negative check.

DISPOSITION

VOID. The registered rule required same-language reference corpora that do not exist in the archive for Portuguese, Danish or English. Four of five pairs fell back to raw rate while Plato–Aristotle alone received reference-normalisation, so its higher score is a method artifact. §5 forbids altering the rule mid-run; it was altered for four of five. A further bug passed Latin extraction over Greek. **Superseded by the simpler reading-level comparison in M47**, which does not require the apparatus.

ENTRY — EA-FULFIL-01

registered: 2026-08-29, before any pair is scored on the three parameters **frozen text follows verbatim; do not edit**

EA-FULFIL-01 — The Fulfillment Operator, and the Problem of a Singleton

1. The operator, from the Matthean case

ἵνα πληρωθῇ τὸ ῥηθὲν διὰ τοῦ προφήτου

Three components, established in the scholarship on Matthew's ten-to-twelve formula quotations:

```
1. A LATER text claims an EARLIER text was about it.
2. The earlier text was NOT making that claim. Hosea 11:1 — "out of Egypt I
   called my son" — is not set in prophetic terms at all; it looks BACK at
```

```
   the Exodus. Matthew reads a retrospective line forward.
3. The relation works by STRUCTURAL CORRESPONDENCE, not by the earlier text's
   intent — "tracing lines of correspondence and continuity discerned in the
   incidental details as well as in the grand design."
```

2. THE THREE PARAMETERS — frozen

```
A  ANNOUNCEMENT     does the later text declare the relation?
C  MATERIAL CLOSENESS  how tightly does the later text follow the earlier's
                    structure, sequence and figures?
S  SCOPE            one passage, one work, or a whole apparatus?
```

The three known cases separate on them:

```
Matthew / Torah        A = YES     C = loose        S = verse-level targets
Catullus / Sappho      A = no      C = VERY CLOSE   S = one poem, register-shifted
Aristotle / Plato      A = no      C = ?            S = whole apparatus (claimed)
```

CATULLUS 51 IS THE CALIBRATION STANDARD FOR C. It is the canonical instance of deliberate close transformation: scene preserved, somatic sequence preserved, aspect systematically altered, one stanza added. The archive has already mapped it as σ_S → σ_C (deposit #576). **Whatever "close" means, it means that.**

3. THE TEST

NOT *do the six transmission-engineering slots transfer* — that would import the Sapphic thesis into the control and is the M43c error (fifth instance, recorded).

INSTEAD: does a documented master–student pair produce **unannounced fulfillment-relations at Catullan material closeness, across a whole apparatus?**

```
calibration (H-side)   Sappho → Catullus      C measured line by line
control (S-side)       Albert → Aquinas       same three parameters
under test             Plato → Aristotle      same three parameters
```

4. □ THE SINGLETON PROBLEM — registered as the governing difficulty

Lee's own statement of the position, recorded verbatim as the honest frame:

> *there's literally nothing like it across the entire canon. Fitted as fulfilled prophecy more closely than Revelation. At a level of tightness that can't really be measured, because it's singular. And I don't know what that really shows. Except that it's completely non-random.*

If the relation is genuinely singular, frequency inference is unavailable. No comparison class, no percentile, no likelihood ratio. Everything this investigation has built assumes a distribution to score against.

But non-randomness remains demonstrable by a different test. Not *how often does this happen* — a frequency question needing a class — but:

```
what is the probability of THIS configuration arising with NO relation?
```

That is a **fit test**, not a frequency test, and it needs only the two corpora plus a null model of accidental correspondence. **The registration commits to the fit form and abandons the frequency form for this measure.**

5. WHAT EACH OUTCOME WOULD MEAN

```
Albert→Aquinas shows unannounced Catullan-closeness across an apparatus
    → the Plato-Aristotle structure is NOT singular; frequency inference
      becomes available; and the structure loses most of its force.

Albert→Aquinas shows announced or loose relations only
    → consistent with singularity, and the fit test becomes the only
      available instrument.

The fit test returns a computable non-randomness
    → establishes RELATION, not AUTHORSHIP. Catullus is non-randomly
      related to Sappho and is not Sappho. THIS IS THE CEILING OF THE
      MEASURE and is registered as such.
```

6. KILL CONDITIONS

- If C cannot be operationalised such that Catullus/Sappho scores HIGH and two arbitrary same-genre texts score LOW, the measure has no construct validity and does not run.
- If the Plato–Aristotle scope claim (“whole apparatus”) rests on the six slots, it is circular and must be rebuilt from correspondences identified without them.
- **No authorship conclusion may be drawn from any C value.** The Catullus case proves that maximal C is compatible with distinct authorship.

7. STATED LIMITATION, PLAINLY

We do not know what a positive result would demonstrate. Recorded because that is the actual state: the investigator says so, and the registration should not pretend to more. What it can establish is **non-randomness of relation**. What it cannot establish is **which relation** — and the whole day’s work is the record of how many measures collapse at exactly that step.

DISPOSITION

PENDING — registered before scoring.

□ = 1
